The capacity of children as agents is often associated with proposals to incorporate the instrument of “media literacy” education in policy. Media literacy education is an information-based activity where health promotion tools are used to provide children (and their parents) with sufficient knowledge and skills to navigate and evaluate mass media of different kinds, which includes marketing messages. The media literacy view suggests that children will be exposed to marketing regardless of policy restrictions, so they are best suited to deal with that marketing as engaged and informed consumers.

It is worth mentioning that much of the health debate about childhood – and even adult – agency in relationship to marketing deals surprisingly little with civic participation. Whereas ordinary children and their parents can be empowered in terms of their informed participation in consumption in markets (such as through media literacy), the options for their involvement in deliberating upon or setting public policy appear to be more limited. This is consistent with the current dominant normative frameworks in the health sector dealing with relationships between state, market, and citizen.

Fifth, the policy principle of liberty raises a set of important issues to consider in public health policy debates. Liberty has been used in the policy debate in the negative and positive sense and is also discussed in parallel with concepts of bounded rationality and of personhood. One line of argument, for example, notes that marketing interferes with individual liberties, whether on the part of the child or parents, because it prevents people from acting freely in their own best interests. This can be consistent with bounded rationality because individuals cannot reasonably, even if they were to be exposed to all possible information, incorporate these considerations into every decision. Another line of argument suggests that marketing is a communication tool, and thus upholding liberty should mean free access to all possible information about products, including marketing. This requires individuals to be more than boundedly rational.

Liberty is also discussed alongside the concept of personhood for corporations. In the US policy

debate on this issue, an argument has been made for minimal policy intervention on the basis of the concept of corporate free speech.

Finally, a sixth set of issues is about marketing and advertising as part of the social and cultural environment. Some actors would argue that marketing has, for some time now, been part of normal childhood experience, and will always be. Other actors would counter that the intensity, frequency, and techniques of marketing have shifted substantially over the twentieth century, meaning that yesterday's advertising directed toward children cannot be reasonably compared to today's (and tomorrow's). Hence, a new policy approach is needed to address what has become an entirely different social and cultural enterprise.

Discussion of marketing in the environment is also related to the debate about commercial presence in different settings. For example, schools, where children not only spend time but are often required to spend time by law, are often seen as an archetypal "commons" that should be free from market incentives or commercial influence.

Gender Dimensions

Gendered advertising refers to images and concepts that are employed in advertising or marketing depicting stereotypical gender roles and or displays. Unlike the concept of sex, which refers specifically to the biologically based differences between females and males, gender is a socially constructed notion that interrogates the juxtaposition between femininity and masculinity.

The current policy debate on food and beverage advertising to children has tended to underexamine the implicit gendered notions in advertisements, marketing practices, and different policy intervention options. Considerations of gender are significant because they contribute directly to the normative frameworks (including commonly held beliefs, values, emotions, attitudes) underlying policy and that perpetuate dominant societal views (e.g., either compliance or aversion). In other words, advertising acts as an important tool of socialization in modern industrialized societies, maintaining particular social

constructions such as gendered relations, displays, and roles in the public policy domain.

As the perceived primary providers of food and care to their families and children, marketing that has been specifically directed to parents has contributed to the normative expectations of what mothers' (as well as fathers' and lone parents') primary responsibilities and obligations ought to be. These expectations extend to socially defined perceptions of what individual children and "family units" ought to do, how they ought to look, and what they ought to eat. The mothering role also holds significance in the context of the childhood obesity rationale for intervention, mentioned above, which has been a subject of interest within the critical feminist perspective on fat studies, including concepts of fat oppression, (lone) motherhood, and constructions of beauty.

For instance, an advertisement depicting a socially acceptable, well-put-together mother, lovingly giving her well-behaved, adorable children a particular food item that they were specifically requesting, and subsequently thoroughly enjoy, creates the expectation that a "good" mother *should* provide certain food items at her children's request in order to achieve the desired outcome of having well-behaved, satisfied children within a happy family. Simultaneously, a child viewing the same advertisement may be conditioned to believe that they might be happier if they modeled the behavior of the children they saw in the advertisement and pressured their mother (or father) to purchase particular food items that were specifically featured. As noted above, a particular area of marketing specialization has been to target "superconsumer" units involving a compound form of consumption made up of behaviours of parent and child.

In addition to advertising that is infused with notions of gendered relations, displays, and roles, normative constructions have also materialized through food products that have been saturated with stereotypical feminine or masculine, or sexualized features/characteristics. Studies have examined gendered packaging directed primarily at young girls or boys, creating a gender bias toward specific food products (e.g., see IOM 2006).

Apart from gender bias created by particular food products featuring specific packaging, other research has examined food advertisements directed at children that are perpetuating gender bias through the following vehicles: gender-specific voice-overs, dominant product user/main character, degree of activity/behavioral aggressiveness, and soundtrack volume – to name only a few (see Childs and Maher 2003). Once again, these factors foster gendered food preferences among specific target consumers such as parents and their children.

As technological advances in the twentieth and twenty-first century have made “screen time” more readily available and as most parents become progressively stretched for time, energy, and resources to manage activities in the private sphere, digital screens – and the advertising on them – have taken on a role of their own and have been equated to modern-day “babysitters.”

Overall, the existing array of policy interventions to address food advertising to children have concentrated upon the private sphere, namely, marketing within homes on televisions. This portrays the management of exposures and behaviors related to advertising as a something essentially negotiated between parents and children. As the perceived or expected dominant figures of authority within the home, parents, and more specifically mothers, are thus expected in most policy debates to be the primary gatekeepers that filter advertising at all.

[Emergency food](#); [Food assistance](#); [Food donations](#); [Food dumping](#); [Food poverty](#); [Food security](#)

Introduction

Food aid refers to the international forms of donating food from one country (or institution) to another without conventional economic

transactions and market mechanisms. In the recipient country, the food may, however, be further sold. A distinct form of food aid where food charity organizations or similar actors distribute food (through for instance food banks) specifically for citizens or households living in poverty, see the entries on “► [Food Assistance](#) and ► [Ethics of Food Charity](#).”

Food shortages have been tragedies characteristic of the history of humanity, but today's situation is different and morally relevant because there is enough food to feed everyone. Still, in 2017, around 800 million people suffer from chronic malnutrition and 20 million are on the verge of starvation. The high prevalence of long-term malnutrition is especially a problem of developing countries and regions burdened by unfavorable agricultural conditions in combination with weak capacities for importing food. In contrast, short-term crises caused by, for example, natural disasters may hit practically any community. Food aid may have existed as a practice for a long time, but the establishment of The World Food Programme (WFP) in 1961 marks its global institutionalization. In 2016, the organization had the overall funding of ca. 6 billion US\$ and assisted over 80 million people. The WFP is responsible for organizing a great deal of the international food aid, especially in the cases of emergency. In terms of per capita donations, the US and Canada are the most significant food donor countries (Oxfam 2005).

Food aid can be categorized in two main types: emergency and long-term. Emergency food aid (see also “► [Food Donation/Emergency Food](#)”) helps in the cases of unanticipated crises that emerge due to natural disasters or human-made catastrophes like war. Emergency aid is often associated with the images of airplanes dropping food packages to inaccessible areas, though the practices are more diverse than that. Long-term food aid, in contrast, is given to areas where hunger or malnutrition has become persistent. These areas are often characterized as poor and developing. Long-term food aid can be provided in different forms; in the early days, it was often *program food aid* where a wealthy country donates food to the recipient for free or sells it

for a very low price on a bilateral government-to-government basis. Nowadays, an increasing amount of food aid is *project food aid* that is linked with broader developmental goals and development assistance. The distinction between emergency and long-term food aid is not always clear since sometimes temporary crises give rise to chronic problems and emergency food aid becomes continued over time. Yet it is important to distinguish between these two main types of food aid, since the moral considerations differ from each other significantly in these cases (Thompson 2010).

Food aid is a multifaceted and contested issue. The basic idea of helping communities who face hunger or malnutrition is in principle broadly endorsed, and many consider it even as a moral obligation of wealthier countries to do something for the situation. Yet, food aid has also generated a lot of criticism from various ethical standpoints. International food aid is also essentially linked with other ethically important questions such as development aid, international trade, and food sovereignty.

Food Aid: Moral Foundations and Goals

Food is vital for human life in all circumstances and the right to adequate food is a universal human right. The necessity of food evokes strong basis for the argument that it is a moral obligation to provide food for a person in acute hunger by anyone capable of helping. Already the Western classics of political philosophy from Thomas Aquinas to John Locke pointed this out. In the modern global ethics, Peter Singer's formulation of the same idea has become widely cited. Singer discussed the East Bengal famine and formulated the utilitarian principle to guide individual action: “if it is in our power to prevent something bad from happening, without thereby sacrificing anything of comparable moral importance, we ought, morally, to do it” (Singer 1971, 231). Hence, we should help people who suffer from hunger, since the costs of helping are very low in comparison to how much it can alleviate suffering.

Philosopher Thomas Nagel (1977) characterized the global situation as radical inequality; those at the bottom are in direst need, those on top experience luxury, and the total supply (of food) would be sufficient for eradicating the severe deprivation without causing destitution to those who are better off. Nagel argues that radical inequality is unacceptable regardless of who has caused it, and it is our moral duty to address it. Both Singer and Nagel emphasized that helping those who experience hunger is an issue of moral obligations, not just a matter of charity. In public discourse, famine relief was often framed as a charity issue. The rhetoric of charity, however, implies that while helping is praiseworthy, not helping is not blameful. Moral obligations are more demanding; omitting them is wrong.

The weightiest normative reasons for food aid relate to our duty to alleviate suffering and prevent unnecessary deaths caused by hunger. This argument does not, however, tell anything about how the duty should be fulfilled or who are primarily responsible for that. Paul B. Thompson (2010, 221–222) argues that foodstuff is a proper way to help only in the cases of emergency; such acute needs are immediate and cannot be satisfied with any other means. Thompson emphasizes that in the case of longer-term problems, food is always at most a partial solution and the response to hunger must take a broader, holistic approach.

The objectives of food aid, whether emergency or long-term, can be described with multiple conceptual frameworks, such as that of human rights (the objective to secure the universal human rights to everyone) or Kantian ethics of respect (human beings cannot act equally as autonomous persons if some starve while others live in luxury). Arguments that explain why we are obliged to alleviate the malnutrition or hunger have been articulated by a multitude of moral philosophers, and they are often linked with the broader question of poverty alleviation (see e.g., Pogge 2002; Singer 2009). Overall, the fundamental objective of the food aid is to secure necessary preconditions for human life. At a higher level, the objective is also to promote the preconditions for an active human life, equal agency, and opportunities for

well-being. Moreover, alleviating hunger helps promote peace and stability in societies.

Donors may also have a wholly different kind of (non-normative) *rationale* for donating food: national self-interest. Already before the WFP, the USA had signed the Agricultural Trade Development and Assistance Act in 1954. Under this Act, it exported food to poor countries with special conditions and prices that were lower than in conventional markets. The rationale was to expand trade and resolve the problem of domestic surplus production (which was mainly a result of volume-based agricultural subsidies). In the domestic markets, the surplus creates a risk of price collapse that would be detrimental for the US farmers. A common way to address this problem was to export surplus to poor countries, framed as food aid; it was difficult for the recipients to refuse from taking foodstuff when their people experienced hunger. Such practices can be criticized from multiple normative aspects, which are discussed later in this entry.

The Criticism of Food Aid

Although the provision of food for hungry people is in certain circumstances considered as a moral obligation, food aid has also received a lot of criticism in ethics. Grounds for the criticism vary and relate to different types of food aid. There is a great variation in the ways to give food aid, in relations created by such practices (like whether there are conditions attached), and in the broader context of aid provision. This section introduces the major strands of normative criticism of food aid. Some other aspects, such as nutritional and environmental issues related to food aid, could also invoke interesting ethical questions but they are beyond the scope of this entry.

The first critical remarks on food aid involved a doubt that the idea of feeding hungry people was overall objectionable. The discussion is known as Singer/Hardin debate (Thompson 2010). The rapid human population growth made the challenge of feeding all people and the environmental sustainability of population growth topical concerns. Biologist Garrett Hardin linked these

matters to food aid and considered them as reasons to rebut Singer's argument that we have moral duties to help starving people. Hardin (1974) argued that the only way to avoid catastrophic population growth beyond the Earth's ecological carrying capacity is to restrict population growth by all means, and this involves *not* helping hungry people in poor countries. Hardin argued that this strategy, though harsh, is the only way to avoid even greater future catastrophes. Hardin opposed food aid because it helped save lives in countries where population growth is (or was at those times) higher than in wealthy countries. Afterwards, Hardin's arguments have been rebutted on both moral and empirical grounds, and the contemporary discussion on the ethics of food aid does not question the justifiability of food aid in general but examines different ways to do it and rationales behind it.

Emergency Food Aid: Problems in the Practices

The need for emergency food aid arises out of unanticipated disasters that can usually be considered distinct, one-off problems of harsh luck that do not involve more complex socio-structural or ethical connections. For these reasons, there appears to be a largely unanimous view that providing emergency food aid is good and even a moral obligation, and the related criticism focuses on rather detailed matters concerning the ingredients or practices of helping.

Giving in-kind aid (providing the aid in the form of foodstuff) has been criticized even in certain cases of emergency aid. In particular, providing food that originates from the donor country is a slow and expensive way to help. First, it often makes the provision very slow since distances between donors and recipients are often great (there are exceptions to this). Second, in some nations the transportation costs may take up to 40% of the funding for food aid (Oxfam 2005), and arguably greater good could be done with the same money if there were less transportation involved. Due to this criticism, it has become more common that donors purchase the provided food from sources closer to the recipient. Not all donors are motivated to do this, though, since the

provision of donor-originated food has also served the purpose of getting rid of domestic surplus production and the use of domestic transport companies returns part of the food aid budget to domestic business.

Another point is that food is not always the most effective ingredient for help even in the emergency areas. Sometimes the provision of cash or vouchers is sufficient and a much faster way to help. This is the case when there is still food available on the markets relatively close to the disaster area, and the victims can do well if they are provided some resources to acquire that food. The distribution of money or vouchers has also become faster due to smart technologies.

One worry that relates to food aid in humanitarian crises, both short- and long-term, is that the help may end up in wrong hands. The food aid distributed to corrupted governments may never reach the hungry mouths; it might be traded for military equipment instead or the provision of food is strictly controlled by the government as a means of exercising power over its hungry citizens. The food itself is also a kind of weapon since hungry people are easier to control and lack capacities for resistance. After the early years of food aid and failures regarding the corruption in recipient countries, lessons have been learned and more attention has been paid to the targeting of food aid.

Long-Term Food Aid and Local Production Capacities

The ethical issues related to food aid are different and more complex in the case of long-term food aid, where the chronic nature of the problem implies other persistent problems and signifies that different kind of solutions are required (Thompson 2010). The continuity of hunger indicates the existence of various factors that prolong the problem; they may relate to economic performance, great inequalities, governance, problems in the food system, and agricultural practices or the lack of capacities to adapt to climate change – just to mention some. In such cases, the mere provision of food is never a solution in itself. This argument resembles the point made in the Chinese proverb “give a man a fish and you feed

him for a day; teach a man to fish and you feed him for a lifetime.” While the proverb is simplistic, it captures a relevant idea. Responsible long-term food aid should focus on building capacities of the recipient community (to produce or procure food on their own) rather than on providing food itself.

The provision of food aid may sometimes be even harmful for the recipient community. In the cases of prolonged malnutrition, the local food production is usually disrupted in one or multiple ways. The problem is that some practices exercised under the banner of food aid hinder the local communities from rebuilding their capacities to produce food. When free or nearly free food – the food provided for aid – enters the local food supply space, it has a price-depressing effect that also influences the income of local producers. Consequences for the farmers may be catastrophic; they are unable to compete with free food, they lose their income, and some will lose their ability to continue farming. The local food production declines and the community becomes increasingly dependent on imported food. In the worst cases, a significant volume of surplus food from industrialized country has been provided during the recipient’s harvest season. Local food may decay in the fields because there are no resources to store it properly for longer periods and it is economically attractive, in the short term, to use the donated food. From the normative viewpoint, food aid that harms the recipient’s food production capacities and local livelihoods (in the ways described above) is ethically unsustainable.

In the early decades of food aid, a major problem was that the main ingredient of long-term food aid was the domestic surplus production of the donor countries, and food aid was based on the rationale to get rid of that surplus. These practices were open to a threefold critique; food aid was given for wrong reasons (national self-interest), it was given in the wrong form (donor’s own surplus), and its consequences were morally unacceptable (further worsening the recipient’s capacities to produce food and provide livelihood for the farmers). The criticism pointed out that such practices should be called hidden dumping

rather than food aid (Oxfam 2005; see also “► [Food Dumping](#)”). Since the early years, the proportion of surplus-based program food aid has significantly declined after its justifiability was put under the microscope even in global roundtables, and it was generally accepted that the food aid should not harm the local food system in recipient countries.

Food Aid, Power Inequalities, and Food Sovereignty

Factors that make malnutrition a persistent problem in a given area remain unless the provision of aid also strengthens local capacities; problems return after food aid is discontinued. Dependency on food aid also creates vulnerability to fluctuations in food aid volumes. These factors evoke a risk that the poor countries’ dependence on food aid and vulnerability increase hand in hand. Relations built on dependence manifest power inequalities, and countries that depend on food aid are also susceptible to the political and economic control exercised by the donors. Food aid becomes a means of control and a way to maintain power inequalities. The second wave of the literature on food aid and ethics has paid attention to these issues, and the food sovereignty discourse has been a focal arena for addressing power relations.

Food sovereignty means the right of peoples or nations to make decisions on and control their own food production, trade, and culture (see also the entry for “► [Food Sovereignty](#)”). The food sovereignty movement was born as a counterforce that opposes the current global and neoliberal food governance (Wittman et al. 2010). The movement argues that the prevailing modes of international food aid maintain power inequalities and undermine the food sovereignty of recipient countries; donations are more harmful than helpful for recipients (Bello and Baviera 2010). Because of these effects, food aid relations can be viewed as an instance of injustice; they maintain and produce inequalities especially between the wealthiest industrialized countries and the developing world.

Unequal relations are reproduced by other mechanism as well. When industrialized countries

dump their surplus production, they also externalize the market-distorting effects of their own production and subsidy system to developing countries. At the same time, the economic structural adjustment programs used to associate the development aid and international funding to the conditions of cutting (for example) agricultural subsidies in developing countries, which increases the plight of the local farmers and reduces their competitiveness against subsidized farmers in global North. This creates a risk that the multinational operators get the control over the food markets and food production in developing countries (Wittman et al. 2010). This may also affect the food culture, since the imported food often differs from the traditional food choices and cultural preferences. Together, these impacts undermine the food sovereignty in the recipient community.

The case of Mexican maize illustrates the complex linkage between inequalities (Bello and Baviera 2010; Wise 2010). After the establishment of the North American Free Trade Agreement, the US started to export surplus maize to Mexico with a price below the production costs. This influenced market prices and put local farmers under pressure since they were unable to compete with the set prices. According to estimates, 2 million people were displaced from farming and the cost of US maize trade to Mexican corn farmers was 6.5 billion US\$ (Wise 2010). The plight of farmers created import dependency on the Mexican staple food. Simultaneously, structural adjustment programs that were purported to support the economic development in Mexico led to the cuts in agricultural subsidies and reprivatization of communal property from small-scale farming to large-scale enterprises. The events that began from what was called food aid created together a vicious circle that maintains food insecurity, farmer poverty, and dependence on food imports.

Improving and Reframing Food Aid

Food aid practices can be improved to make them a viable means for promoting the food security, well-being, and equity of people, rather than a

means of dumping surplus or creating and maintaining inequalities. In the case of the emergency food aid, it has been proposed that a great deal of the problems could be resolved by providing food aid in the form of cash transfers rather than food (Oxfam 2005). Monetary aid is faster and it would allow purchasing the food from local or regional markets (within the limits of availability), which would support local markets as far as possible. Moreover, it would allow the recipients to exercise food sovereignty through expressing their food preferences in procurement decisions, instead of depending on whatever food the donors provide. If the donors give in-kind aid, they should purchase it from the local or regional markets rather than export their own food commodities. Still, the in-kind food aid donations largely originate from donor countries (up to 90% according to Oxfam 2005). As an exception, The World Food Programme states in its online reports that it sources a majority of the provided food from actors close to the operation locations.

Other suggestions for making food aid ethically sound concern long-term food aid and relate to the broader, multifaceted context of development assistance. In essence, the food aid should be only a part of a broader project and the overall focus should be on building local capacities, fostering agency, and providing the resources and skills of local people. What this means depends on local circumstances, but a holistic approach might involve, for example, providing resources (seeds, tools, information, and infrastructure) that support local food production and storage. Local participation in designing the implementation is also essential to ensure that the local traditions and cultural values are respected.

Conclusion

Food aid refers to international relations where particular countries (or communities) receive food-related aid from donors to alleviate the hunger or malnutrition in the recipient areas. Donors can be either countries or humanitarian organizations like The World Food Programme. There are two different types of food aid: emergency food

aid is provided in the cases of unexpected natural disasters or humanitarian crises, whereas longer-term food aid concerns situations where the problems have become prolonged. Moreover, food aid can be provided as in-kind aid (foodstuff) or in other forms as well. Long-term food aid can be classified into program and project food aid. Program food aid is provided on a government-to-government basis and usually consists of donor's domestic surplus production. This kind of food aid has received much criticism in ethics, because it is based on wrong motives (dumping surplus) and tends to have harmful effects on the recipient (displacing local production, distorting markets, and preventing capacity building in the recipient country). Recently, there is a shift from program food aid to project food aid. The latter is associated with the broader context of development assistance. Project food aid is conducted as a part of development projects that search to promote capacity building in recipient communities. Project food aid is more favorable from the ethical viewpoint. It is nevertheless important to promote the local participation in the projects to make sure that food aid does not create or maintain unequal power relations between countries or undermine the local food sovereignty.

Food Allergies: Ethical Issues

Kristina M. Nies
Cambridge, MA, USA

Synonyms

Anaphylaxis; Diet-related disease; Food intolerance; Food sensitivity

Introduction

Food allergy is the term used to describe an immune response to a protein found in a food. This adverse reaction is caused by a food that is normally tolerated by humans. (Food allergies occur in other species, but will not be discussed here.) There is no cure for food allergies. Treatment options include avoidance, desensitization,

and/or treatment of symptoms. Persons with severe food allergies can experience anaphylaxis, a life-threatening impairment of the circulatory and respiratory systems that can lead to death. The allergic reaction occurs when IgE (immunoglobulin E) antibodies “tag” or attach and mark the protein as a foreign pathogen and trigger the allergic response in the body.

Food allergies most often occur during the first or second year of life. While it is possible to outgrow food allergies, allergies to tree nuts and peanuts are almost never lost. Food allergies are prevalent in 6–8% of the population during the first year of life, and rates fall off and remain about 1–2% of the population (Wood 2003, p. 1631).

The most common food allergens are often informally referred to as the “top 8” and account for ~90% of food allergies experienced. They are peanuts, tree nuts (including almonds, pine nuts, coconuts, walnuts, pecans, pistachios), eggs, milk, soy, wheat, shellfish, and fish. Other less-common food allergens include fruits, vegetables, grains, spices, natural colors and even synthetic colors, and food additives. The 2004 Food Allergen Labeling and Consumer Protection Act (FALCPA) was passed by the US Congress in 2006 and requires the “top 8” allergens to be listed on packaged foods regulated by the Food and Drug Administration (FDA).

Food Allergen Exposure and Symptoms

Persons with food allergies can experience allergic reactions stemming from skin contact, ingestion, and/or inhalation of the allergen. There are varying degrees of sensitivity that food-allergic persons experience. The most severe sensitivities result in immediate hypersensitivity reaction referred to as *anaphylaxis*. This is classified by acute symptoms (appearing in the first 30 min after exposure, though symptoms will likely be present within seconds) and delayed symptoms (experienced up to 8 h after exposure). While immediate reactions including breathing difficulty or angioedema may be life-threatening, delayed reactions are usually not so.

Allergic symptoms include:

- Flushing, urticaria/hives
- Itching of mouth, lips, tongue, eyes, and skin
- Tearing of the eyes
- Angioedema, swelling of lips, palate, tongue, eyelids, or entire face
- Congested or runny nose, rhinitis, sneezing, rhinorrhea
- Stridor, wheezing, shortness of breath
- Difficulty swallowing
- Upper airway obstruction, dysphonia
- Hypotension, arrhythmias, hypovolemic shock
- Chest pain
- Nausea and/or vomiting
- Abdominal pain and cramping
- Fecal urgency or incontinence
- Uterine cramping
- Urinary urgency or incontinence
- Fainting
- Cardiovascular collapse

Eighty percent of persons experiencing anaphylaxis have skin symptoms.

An allergic individual may experience different symptoms in response to the same allergen, over multiple exposures. These symptoms may change in type and severity as the person ages (Sampson et al. 2006, p. 374).

Diagnosis

There are three forms of allergy testing used to determine if a person has a food allergy: blood test, skin prick test, and oral food challenge.

Blood tests come primarily in the form of the IgE (immunoglobulin E) antibody tests. IgE tests are conducted by taking a sample of blood, introducing potential allergens to the sample, and measuring the IgE levels. A significant benefit of testing a drawn blood sample is that multiple allergens can be tested at once without exposing a person to the possibly toxic substances.

Skin prick test involves a portion of the allergen being placed on a needle or directly on the surface of the skin and the needle puncturing the skin. If a hive appears at the puncture site, the

person is considered to have an allergy to the allergen. Skin prick tests are often performed on the forearm or back of the person being tested. Several tests can be done simultaneously using a paddle or plate holding several samples at once. Skin prick tests have an ~85% sensitivity.

An oral food challenge is when a person is given an allergen in pill form to be ingested. This is often done in the office of a physician or allergist so the person can be carefully monitored in case of anaphylaxis. There has been a move to make the double-blind, placebo controlled food challenge the medical standard for food allergy diagnosis. This method is not feasible for those with a known medical history of allergic anaphylaxis. The diagnostics used can vary between different medical sites and clinics, which leads to a different standard of care. The lack of universal standards and unequal access to care are two important ethical issues.

Cross-Reactivity

Persons with a known allergy to one (or more) allergen can experience “cross-reactivity.” This is an experiencing symptom of an allergic reaction in response to an exposure to an allergen that the person is *not* allergic to. Examples include latex-allergic persons having a histamine reaction to certain fruits. Persons who are allergic to bananas can also have a cross-reaction with latex.

Treatment

While there is no known cure to food allergies, there are two main treatments available for allergies: avoidance or controlled exposure and desensitization therapy.

Avoidance is the process of avoiding all exposure to allergens and control any unwanted exposure by managing exposure symptoms. There are three types of medications used to manage allergy symptoms: epinephrine, antihistamines, and steroids.

Epinephrine is a medication used to treat the acute symptoms of severe allergic reactions. It is

often administered in the form of an epinephrine autoinjector (also known as EpiPen), a self-injectable form of adrenaline. It is administered when a person is having an immediate hypersensitivity reaction, which is often life-threatening. The goal is to prevent or preempt anaphylactic shock.

Antihistamines are another treatment option for managing the symptoms of an exposure to an allergen. Antihistamines block histamines and histamine reactions and can relieve some symptoms including itchiness. The most common antihistamine is diphenhydramine, commonly known as Benadryl. Antihistamines are not fast-acting and thus are ineffective if administered during an immediate hypersensitive reaction.

Steroids are a treatment option used to decrease inflammation that occurs during and after an allergic reaction has occurred. Similar to antihistamines, they are not effective in preventing or treating anaphylaxis.

Oral immunotherapy, or desensitization, is not a cure but a treatment where persons with food allergies are exposed to small amounts of the allergen. Over time, the quantity of the allergen is slowly increased, with the goal of desensitizing the person to the allergen. Allergy shots are another form of desensitization therapy typically used for environmental allergens. They are not considered effective for food allergies and not a treatment option.

Food Allergies Versus Food Intolerances

Food intolerance is a broad catchall term used to define an adverse experience to a food. Food allergies are classified differently than food intolerances. Food allergies involve an IgE-mediated response, while food intolerances do not. Food intolerances can involve the immune system and many involve an IgG- and/or an IgA-mediated response to a food protein, such as Celiac disease or Heiner syndrome. Food intolerances also include nonimmune system responses to food, e.g., lactose intolerance which is an inability to digest lactose due to an insufficient amount of the enzyme lactase.

Food Allergies, Ethical Considerations

There are two categories of ethical concerns regarding food allergies: the personal and the implications to society. While persons with food allergies may endeavor to address their individual quality of life concerns, food allergies pose several public health concerns and bring issues of food and healthcare access into question. Lack of access to healthcare can be an obstacle to diagnosis and allergy treatment and potentially lead to increased emergency room use and/or mortality rates. On the individual level, food allergies also impact the quality of life of the food allergic but also caregivers. Quality of life measures include general health and emotional health including stress levels, limitations on family activities, and emotional impacts on parents (Sicherer et al. 2001).

Social Determinants of Health and Disparities

When looking at the ethics of food allergies, we must consider who has access to information about food allergies and who has access to testing and medications to manage symptoms. Social determinants of health and disparities dramatically impact access to healthcare. The World Health Organization defines social determinants of health as “the conditions in which people are born, grow, live, work and age. These circumstances are shaped by the distribution of money, power and resources at global, national and local levels.”

While it is easy to use the term “social determinants of health” to encompass all aspects of an individual’s life and his/her surroundings, it is important to acknowledge the specific factors that impact health. These elements translate to variability in the quality of health services and support. This variability in access and quality is known as *healthcare disparities* and is defined as being those attributes specifically stemming from race and ethnicity. In addition to race- and ethnic-based disparities, access to care and quality care is impacted by socioeconomic factors, location, class, gender, sexual identity, religious affiliation, age, language spoken, and education.

Access to Food

There are significant obstacles to maintaining safe food. Ensuring food is allergen-free is difficult because the proteins that cause allergic reactions are not visible to the naked eye. Cross-contamination by crumbs, shared preparation facilities, and lack of proper sanitation, all can cause safe foods to become contaminated. Packaged foods that are labeled allergen-free are often significantly more expensive than their counterparts. This increase in cost can be financially burdensome or even prohibitive.

Education and Support Groups

There are many organizations and support groups who advocate on behalf of the food allergic. Some of these groups also function as emotional and educational support networks. Many have free membership but all require the social capital of time and often access to computers and the Internet. These requirements can exclude many who are in need of information and support.

Legal Rights

Laws that define and require food labeling are essential for those with food allergies to be able to have access to safe food. It was not until recently that some protections have been provided by US law. Passed in 2004 but not enacted until 2006, the Food Allergen Labeling and Consumer Protection Act of 2004 requires that source ingredients for the top 8 allergens be listed in plain English on packaged foods for sale in the United States. The second phase of the law was to develop a definition for the term “gluten-free.” This was not completed until August 2, 2013, when the FDA released the federal definition that the food must contain less than 20 ppm of gluten in order to use the term “gluten-free.”

This law pertains to packaged food items only. The regulations do not apply to alcoholic beverages and prescriptions or over-the-counter medications. Many pills are formed with starches that are used to bind medications. Some injectables, such as vaccines, have egg-based serums. Since there is no legal requirement to disclose the origin

or source of ingredients, medications can be a source of potential unknown allergens.

In December 2012, the US Department of Justice announced that food allergies may constitute a disability under the Americans with Disabilities Act (ADA). The ruling was the result of a lawsuit brought against Lesley University. This ruling had direct implications for university meal plan participation and food services compliance. This ruling allows for some additional legal standing for those with celiac disease and/or food allergies.

In Massachusetts, the Act Relative to Food Allergy Awareness in Restaurants was signed into law in January 2009. It had two provisions that were rolled out separately. In October 2010, a food allergen poster and menu advisory were required by restaurants. In February 2011, “food establishments were subject to a certified food protection manager who viewed the training video and obtained a training certificate.” Some have criticized the law as not doing enough in the way of educating restaurant staff and possibly giving food-allergic patrons a false sense of security in dining out.

An Act to Protect Anaphylactic Pupils: Sabrina’s Law came into effect on January 1, 2006, in Canada. The law ensures all school boards have policies or procedures in place to address anaphylaxis in schools, which include providing instruction to staff and guidance on the administration of medication. (There is no such law in the United States.)

Social Stigma, Dating/Intimacy, Quality of Life

There is often a social stigma surrounding a person once their food allergy has become known. Persons can be excluded from certain events, or their participation is marginalized. Friendships, dating, and intimacy are complicated in the case of severe food allergies when skin-sensitive reactions can come from touching and kissing.

Food allergies can place additional stress on family members and caregivers. There is an increased financial burden due to the need to procure and store safe allergen-free foods; in families, this sometimes means having dedicated allergen-free space and/or different utensils in addition to special foods. Food-allergic people and their caregivers can have higher rates of school and work

absences and limits placed on social interactions. These can lead to significant negative impacts on quality of life (Sicherer et al. 2001).

Literature

As Behrmann points out in his article “The Paucity of Ethical Analysis in Allergology,” there has been little attention paid in the form of academic and medical literature on the ethics of food allergies. His review of texts written in French and/or English resulted in 35 pieces with substantial focus on allergies and ethics. He notes that research is primarily focused on the ethics surrounding psychological issues, and the majority is about asthma sufferers. He calls for the inclusion of social, legal, ethical, and morbidity, to be added to future research. Behrmann makes the comparison to the attention that obesity has received, since both diseases have higher occurrences in industrialized worlds, and both have seen dramatic increases since the 1960s. In his comparison, Behrmann calls for similar attention to be paid toward food allergies – focusing on ethics, public health and public health policy, disparities, and the need to pay specific attention to vulnerable populations. He outlines the need for collaborative research between allergologists and bioethicists to create interdisciplinary research to guide health policies and interventions.

There are significant ethical issues that arise in the diagnostics and treatment of food allergies. Roberts in “Challenging Times for Food Allergy Tests” highlights the ethical need to conduct oral food challenge(s) as a means of ruling out false-positive blood work and unnecessarily restricting diets. Oral food challenges produce the risk of anaphylaxis, which can deter parents of small children and physicians from wanting to undergo the test. Roberts sides with the need to accurately diagnose patients and that the risk is outweighed by the need for knowing what food a person is or is not allergic to and what her/his reaction truly would be if exposed. At the same time, Hourihane and Beirne in “Evidence of Effectiveness of Anaphylaxis Management Plans: Are We Waiting for Godot?” look at whether drug trials for treatment of anaphylaxis are ethical at all.

In the article “Complementary and Alternative Medicine for the Allergist-Immunologist: Where Do I Start?,” Engler et al. (2009) highlight that many food-allergic patients seek complementary or alternative therapies in addition to Western medical practitioners and medications. There is an issue of education, on parts of both physicians and patients as to the safety and efficacy of alternative/complementary therapies. They bring up the need for international information sharing, evaluations, reporting, and research.

Millins’ work calls for an increase in research into the epidemiology of food allergies and notes the dramatic increase in hospitalization for anaphylaxis in Australia. He states that additional research into food allergies is necessary not only to determine their cause but also to effectively gather rates of occurrence and to effectively determine where and why food allergy rates are increasing. The public health implications include allocating additional resources for training and educating medical professionals on the signs of anaphylaxis and how to effectively administer medications.

One of the only pieces looking at the ethics of people with food allergies interacting with those without, and how both of these sets of bodies are being governed, is Ross and Hunt. In their “Governing Peanuts: The Regulation of the Social Bodies of Children and the Risks of Food Allergies,” they look at the school board in Ottawa’s set of guidelines surrounding peanut allergies. They specifically look at the moral implications of shifting the risk management from the food-allergic child to that of the parents of non-food-allergic children and classroom teachers. Ross and Hunt argue that the additional burden of regulating child behaviors and food consumption that is placed on teachers is an extension of the government and part of an increasing trend in teacher responsibility and oversight into more and more aspects of children’s and their parent’s lives.

Summary

The ethical considerations surrounding food allergies are complex and multifaceted. Persons with

severe food allergies are impacted by the food choices and practices of others. When we consider what is just, ethical, moral, and right, we must consider the non-food allergic as well as those with food allergies. In both the public health and public school arenas, food allergies raise significant issues about individual’s rights. This is further complicated by new laws and regulations, which have begun to shift some responsibility onto food producers, school districts, and restaurants, to help mitigate some risks for those with food allergies.

While there is more awareness and regulation, the rates of food allergies are increasing. This raises concerns about access to quality healthcare and brings up questions about what times of medical testing are too risky to engage. There is no known cause or cure for food allergies; and goal of gaining the knowledge of one or both may require continued discussion of the ethics of clinical trials and testing.

Food Altruism

Food offering; Food transfer; Sharing food

Introduction

As species, humans are extremely altruistic. Primates, and although we often act in our own interest, we also have a sincere concern for the welfare of others (Silk and House 2011). In a biological sense, altruism can be defined as “acting to increase another individual’s lifetime number of offspring at a cost to one’s own survival and reproduction” (Krebs and Davies 1993). According to this, altruism is a paradox in evolutionary terms and it seems inconsistent with natural selection. This key mechanism of evolution is not expected to favor indiscriminate altruism, because altruists bear the costs of the altruistic behaviors that they perform; this reduces their relative fitness (Silk and House 2011). Fitness involves the ability of organisms to survive and reproduce in the environment in which they find themselves and, as consequence of this, organisms provide genes to the next generation.

However, different forms of altruism are observed in the nature, for example, the eusocial insects such as termites, ants, and some species of bees (e.g., honeybees), who sacrificed for one

another regularly (Warneken and Tomasello 2009). There also is a growing body of evidence that shows different altruistic behaviors in some species of birds (e.g., crows) and mammals such as lions, wolves, African hunting dogs, vampire bats, some cetaceous, and mainly in nonhuman Primates (de Waal 2000; Jaeggi and Van Schaik 2011). Comparative studies with our evolutionary relatives, especially the great apes, as well as the observation of the traditional human societies (e.g., modern hunter-gatherer and forager-horticulturalist groups), have played an important role on the knowledge of the roots of altruism and in a better understanding of the evolution of cooperation and sociality among our ancestors.

Despite the individual heterogeneity, human altruistic acts as helping, sharing, and comforting are considered by many to be “unique” in the animal world, both at quantitative and qualitative levels (Fehr and Fischbacher 2003). These authors have reviewed the nature of human altruism, pointing out the importance of theories of cultural evolution as well as gene-culture coevolution to explain the features of altruistic cooperation, which is beneficial only to the recipient but not to the actor.

Contemporary neo-Darwinian models of evolution, which define evolutionary success as the survival of one's genes in subsequent generations, generally agree that prosocial tendencies exist in humans because of (i) genetically based predispositions to act prosocially and (ii) evolutionary success of people who displayed such predispositions. There must be some physiological and/or neurological processes that facilitate prosocial behaviors (biological basis) and some of these must be inherited (genetic basis). Nevertheless, although we can be genetically predisposed to act prosocially, we cannot forget the important role of socialization in the development of altruism and that cooperation in human groups is more complex than in the animal world because our species has a strong cultural component (the cultural-ecological niche) and a cognitive flexibility result of a complex brain not found in other animals, even phylogenetically closely related. Thus, although as species *Homo sapiens* is the product of biological evolution, with bodies,

brains, and behaviors modeled by natural selection, an important part of the human cooperation can be considered sociocultural and not only limited to small groups (where there is considerable relatedness) nor to genetically related individuals (as in other organisms).

Warneken (2013) has pointed out: “the altruistic tendencies seen in humans have deep phylogenetic roots, potentially dating back at least to the last common ancestor of human and chimpanzees.” Yamamoto and Tanaka (2009) consider that this common ancestor seldom showed voluntary altruism and this is practically absent in non-human animals. There is also evidence that the ontogenetic origins of altruistic helping and sharing are apparent in early childhood and that human altruism comes in many forms supported by different psychological mechanisms (Warneken and Tomasello 2009; Warneken 2013). Both empathy and sympathy could be considered the major motivations for prosocial behaviors in children, and these positive emotions help to maintain and regulate the complex human social life (Liebal et al. 2014). Through their evolutionary history, human beings have developed a great capacity for empathy and compassion, moral sentiments, and a disposition to enforce culturally specific social norms (Silk and House 2011).

Food (Altruism) Sharing

Among the altruistic behaviors, food sharing is one of the most cited characteristics of human groups; it is considered a universal feature of human forager societies and an important subject of research in the domain of several disciplines as anthropology, evolutionary biology, human ecology, neurosciences, and social psychology, among others. Food sharing has been defined as “transfer of a defensible food-item from one food-motivated individual to another, excluding theft” (Feistner and McGrew 1989). In our species, this form of altruism has been linked to the evolution of sociality, the sexual division of labor, the transition from hominoids to hominids, and morality and even referred to as a prime mover in the transition between protohominids and modern

humans (in Gurven et al. 2000). Food sharing has important implications for the evolution of human cooperation, offering a tool to evaluate the apparent “anomaly” of altruism, whereby a recipient gains biological fitness benefits (i.e., individual reproductive success), at the expense of a donor.

Two main evolutionary processes have been invoked to explain altruistic behaviors, including sharing food: (1) kin selection (Hamilton 1964) and (2) reciprocal altruism (Trivers 1971). Hamilton’s proposal can be expressed by means of the named “rule of Hamilton” ($rb > c$), where “b” is the benefit (in number of offspring equivalents) gained by the recipient of the altruism, “c” is the cost (in number of offspring equivalents) suffered by the donor while undertaking the altruistic behavior, and “r” is the genetic relatedness (the probability that a gene in the potential altruist is shared by the potential recipient of the altruistic behavior) of the altruist to the beneficiary. Kin selection is not based in individual fitness but in inclusive fitness, which is the successful transmission of one’s genes from all sources to the next generation (Hamilton 1964). Consequently, altruistic acts are done to favor the closest relatives as carriers of the same genes as the executor of the action. This is the model that best can explain the existence of individuals cooperating for the benefit of others assuming a certain cost.

The mechanism developed by Trivers (1971) tries to explain altruistic behavior among unrelated adult individuals based on the concept of reciprocity: the subject or actor who takes an altruistic act awaits well rewarded later by the recipient or by other group members. This reward increases the survival and reproductive capacity (fitness) of the actor to medium or long term, but the benefits are less obvious than in the case of kin selection, because they may not appear for some time (or never). Reciprocal altruism requires a “face-to-face society” – where the members of the community (human or animal) know each other and often have repeated transactions with each other – a “memory-based” mechanism, and a certain degree of social stability and tolerance. The kin selection model requires no complex cognitive abilities (excepting a potential ability to distinguish between close genetic kin and non-kin, i.e., “kin

recognition”) and has been reported in many animal taxa (most often between mother and dependent offspring), but explanations for sharing among unrelated individuals are more controversial and less common among other animals, including Primates; in fact, there are relatively few examples of reciprocal altruism and these observations are often difficult to replicate.

Some studies of intragroup food transfers among traditional societies support that reciprocal altruism (in diverse forms) can explain much variation in food transfer patterns, that is, in who gives and who receives specific resources, although not all group members benefit equally from sharing networks (Gurven et al. 2000). The results obtained by these authors, from data collected in a population of Hiwi foragers of Venezuela, indicate that “a complex combination of factors are relevant in structuring food transfers, involving multiple behaviours with multiple motives of potential interactants.” Among the obtained results in this research, the authors indicate that meat was the most widely transferred resource type, the most food transfers in primary sharing events were to middle-aged individuals, and there were no sex differences in food transfer patterns.

Although nonhuman Primates (e.g., African apes like chimpanzees and some Neotropical monkeys) can share food, the range of this behavior is much more limited than it is in humans, and it is typically biased to familiar group members – close kin, mates, and reciprocating partners. This suggests that there may be fundamental differences in the social preferences that motivate altruism across the order Primates (Silk and House 2011). Several authors have pointed out that there are some nonhuman Primates that regularly share food outside the parent-offspring environment: in the field, bonobos and chimpanzees share large fruits and meat, and in captivity they share attractive plant foods. A proposed explanation is that the food sharing (mainly meat, a food that is often the result of hunting by males) among non-kin adults has coevolved with conditions for partner choice and thus the opportunity for reciprocal exchange seems to be a main explanation accounting for the presence of sharing among unrelated adults

across these Primates (Jaeggi and Van Schaik 2011). In chimpanzee males, sharing often occurs among unrelated individuals; therefore, social benefits such as sex, grooming, and reinforcing social bonds have been signaled to explain this behavior; in addition, sharing with non-kin improves popularity and increases status within the group (in Eppeley et al. 2013). Meanwhile, female food possessors of a desired food item tend to share most frequently to close affiliates and offsprings (Eppeley et al. 2013).

Other empirical observations on chimpanzees' altruism and reciprocity indicate that these African great apes do not give food to others in a spontaneous way, that is, without a recipient's request, and they help only in contexts of not involving food, at least when it comes to food difficult to obtain, scarce, and highly energetic as meat (in Yamamoto and Tanaka 2009). In general, the observations about food sharing patterns in Primates seem contradictory and the results are not absolutely conclusive. This may be partly due to the own concept of "sharing food" (different from other non-altruistic behaviors), the conditions of experimentation and the diverse theoretical frameworks, the difficulty of observing animals in the field, and many complex factors that could influence the behavior of chimpanzees in space and time.

The complexity that food sharing shows in humans, the diverse characteristics and individual variation in both social preferences and motivations, and mainly its impact in social life make this altruistic behavior "exclusive" compared to any other organism. In humans, food sharing between mothers and offspring is only not limited to lactation during infancy (nutrition); in fact, human parents feed their children until adulthood in all human societies, modern families of industrialized populations included. Through the intergenerational cooperation (parents, grandparents), food sharing ensures the survival of the child, who is dependent on food provision by others. In a recent paper, Hamburg et al. (2014) have examined the interpersonal and intrapersonal antecedents and consequences of food offering, mainly the emotional component involved in the offer and reception of food. In a development

perspective, they state that the interaction between parent and child at food offering level not only ensures survival of the child, but it may be related to emotion regulation throughout the life span of individual. According to these authors, "children will learn from an early age to use food as a primary means to soothe self and others"; they also propose that sharing food of resources increases interpersonal closeness and can be used to show affection, hospitality, and adhesion to others. "The offer of food by an empathic provider is motivated by the emotional state of one's interaction recipient or partner"; this mechanism is called "emphatic emotion regulation" (Hamburg et al. 2014). Probably, throughout human evolution, these emotions and the perception of each other's needs evolved along with an increasingly large, complex, and flexible brain, which allowed humans a greater reciprocity based on mental scorekeeping (Yamamoto and Tanaka 2009). According to these authors, the use and dependence on tools, an enriched material culture – linked to the development of social systems based on altruism and reciprocity –, the increasing dependence on animal foods, and the articulate language might have promoted the evolution of altruistic and other prosocial behaviors in humans.

A new line of argumentation about how our ancestors would have developed altruistic behaviors related to food sharing can be found in the recent paper of Pontzer et al. (2016). These authors discuss the evolution of human brain size and life history in relation to an increased acceleration of metabolic rate and changes in energy allocation in the human lineage. Compared to great apes (chimpanzees, bonobos, gorillas, and orangutans), humans have large brains and a particular life history, characterized by a high reproductive output, a slow-growth childhood, and a noteworthy longevity. These authors hypothesize that, in humans, sharing energy-dense foods, as meat and tubers, and increased body fat coevolved along with greater total energy expenditure, in order to reduce the inherent risk of increased energetic requirements to maintain the unique features of our species (an expensive brain, a high fertility, great neonates, and extended life cycle).

Conclusion

Food sharing is a fundamental form of cooperation in human beings and it is particularly noteworthy because of its central role in shaping evolved human life history, social organization, and cooperative psychology. It is possible to consider that altruism and reciprocity in humans are somewhat different in quantity and quality from those reported in nonhuman Primates, since the environment, social systems, cognitive abilities, and life history are quite different. In contrast to other Primates, much human sharing is voluntary and proactive and can be observed not only in a parent-offspring context but also among both related and unrelated adults. Humans might have acquired the ability for complex forms of reciprocity and might have achieved societies based on cooperation with altruism after divergence from the common ancestor of humans and other living relatives. Throughout our evolutionary history, the food interchange can be viewed as a survival strategy of individuals in front of the risks of an unpredictable surrounding and a complex social life, as well as to provide extra energy needed for brain expansion and faster reproduction.

Summary

Altruism can be defined as “acting to increase another individual’s lifetime number of offspring at a cost to one’s own survival and reproduction.” According to this, altruism seems inconsistent with natural selection; however, different forms of altruism are observed in different animal taxa, especially nonhuman Primates. Among the altruistic behaviors, food sharing is one of the most widely cited characteristics of human social groups; it is considered a universal feature of human forager societies and an important subject of research in the domain of several disciplines as anthropology and evolutionary biology, among others. Food sharing can be defined as “the unresisted transfer of food from one food-motivated individual, the possessor, to another, the receiver.” This prosocial behavior has important implications for the evolution of cooperation

in our species, enabling the interpretation of altruism, an evolutionary paradox in Darwinian terms, whereby a recipient gains fitness benefits, that is, in the ability to survive and reproduce in a given environment, at the expense of a donor. Although altruistic cooperators may incur small costs in the short term, they may gain greater selfish benefits either by increasing their “inclusive fitness” by helping their kin (kin selection model) and/or by recouping their losses in future interactions (reciprocal altruism model).

The complexity that food sharing shows in humans, the diverse characteristics and individual variation in both social preferences and motivations, and mainly its impact in social life make this altruistic behavior “exclusive” compared to any other organism, but the origin of this altruistic behavior is still debated. Although some of the human cooperation is sociocultural, there must be some physiological and/or neurological processes that facilitate prosocial behaviors (biological basis) and some of these must be inherited (genetic basis). In fact, it has been stated that the altruistic tendencies seen in humans have deep phylogenetic roots, and there is also evidence that the ontogenetic origins of altruistic helping and sharing are apparent in early childhood.

Food and Agricultural Trade and National Sovereignty

State sovereignty; Nationalism

Introduction

National sovereignty is a contested concept. Some see the evolution of the world order since the Peace of Westphalia in 1648 toward a system of sovereign nation states each with “supreme authority” over a particular territory as central to the protection of national identities and the maintenance of peace between peoples naturally inclined toward conflict (Stanford Encyclopedia of Philosophy 2010). Singer, on the other hand, does not see national sovereignty as absolute and argues that it “has no intrinsic moral weight” (Singer 2004, page 2). Respect for national sovereignty may be considered a grave error permitting governments to suppress opposition to their actions or to persecute people who subscribe to different religions or are members of different ethnic groups. In the aftermath of the atrocities of World War II, the international human rights movement has sought to circumscribe the ability of states to violate human rights as defined in the United Nations’ Universal Declaration of Human Rights. While many regimes reject the universality of some or all of these rights and most governments resist any outside interference in internal affairs, global institutions related to human rights such as the UN Convention on Genocide or the International Criminal Court can support efforts to override the absolute authority of sovereign states in certain cases (Van Der Vyver and Johan 2013).

Globalization is another factor eroding state authority. Global problems such as climate change, the spread of infectious diseases, or terrorism cannot be addressed by individual states acting on their own. Rather, they can only be handled through international cooperation which may require subordinating certain national prerogatives to global initiatives. In addition, increasing economic interdependence through trade, investment flows, and migration means that government policies designed to manage the domestic economy are less effective and may be undermined entirely. The tension between globalization and national sovereignty is particularly acute in the area of food and agricultural trade. Food and agricultural systems are important components of national economies, but they are also

invested with significant social and cultural meaning. The sensitivity of food and agriculture is apparent from the history of trade negotiations at the General Agreement on Tariffs and Trade (GATT) and its successor, the World Trade Organization (WTO). Agricultural trade negotiations were the most difficult to bring to conclusion during the GATT Uruguay Round (1986–1994) and have been at the heart of the difficulties in completing the WTO Doha Development Round of trade talks launched in 2001.

National Sovereignty

A common definition of sovereignty is that it is the right to exercise “supreme authority” in a territory or political community (Stanford Encyclopedia 2010; de Benoist 1999). De Benoist (1999) argues that there is a second meaning that concerns the legitimacy of the holder of this supreme authority. In democratic states, the ultimate sovereign is supposed to be the people, but as a practical matter, sovereign authority is generally delegated to a government considered to be legitimate because it has been chosen freely by citizens. Even if the government of a country is considered to be unlawful by its own citizens or by the world community, international organizations such as the UN generally treat standing governments as if they are legitimate. The exercise of supreme authority requires noninterference with a government’s actions both by those within the country and by foreign governments or individuals. Noninterference raises difficult ethical issues in cases where a government is committing genocide or crimes against humanity with respect to individuals or groups residing in its territory. If national sovereignty has no “moral weight,” should it not be overridden by other moral imperatives such as a duty to protect vulnerable populations?

Of course, not all repressive actions by governments represent human rights violations. Most would agree that states have the right to use force to control criminal or terrorist activities. Problems arise, however, when the lines between criminality and the normal exercise of democratic rights

become blurred. The government of Ukraine jailed Yulia Tymoshenko, a former prime minister, on abuse-of-office charges that most considered to be politically motivated, and Russian Federation President Vladimir Putin has been implicated in the murder of Alexander Litvinenko, a political opponent residing in the United Kingdom (Sestanovich 2016). Zanetti (2001) suggests that human rights violations should include not only suppression of free speech or physical violence but also extreme deprivation, hunger, and poverty. Such a position is consistent with the Universal Declaration of Human Rights which includes rights to adequate food and shelter as well as civic and political rights. Pogge (2001) argues that all humans have a right not to be poor, claiming that the cause of world poverty is the global economic system created for the most part by individuals and governments in high-income countries. Full recognition of rights such as these would mean that there is a very extensive duty to assist regardless of the cause of a people’s misery and whether or not the government of the country in question agrees.

Regardless of one’s conclusions about the scope of human rights and the obligations they entail, it is clear that the world community is interfering in the affairs of sovereign states in the name of human rights more regularly than has been the case in the past as shown by recent conflicts in Bosnia, Kosovo, Sierra Leone, Libya, and Syria. These interventions suggest that respect for absolute national sovereignty may be on the wane. Human rights interventions are only part of the global forces working to constrain the exercise of state sovereignty. The ability of governments to control the evolution of their nation’s culture, economic and social life, and legal system is also eroded by globalization as will become apparent in considering international food and agricultural trade.

Food and Agricultural Trade

The experience of the EU with economic integration can offer insights into the trade-offs between globalization and national sovereignty. In 1957,

six European countries (Germany, France, Italy, the Netherlands, Belgium, and Luxembourg) created the European Economic Community (EEC). The EEC represented a fairly low level of economic integration, but over time as membership grew, the benefits of further economic integration were judged to outweigh the costs of reduced national sovereignty. From its inception, some European leaders hoped to see the EEC and later the European Community (EC) become more tightly integrated as a way to promote peace and avoid conflicts such as those that took place in the first half of the twentieth century. By the beginning of the twenty-first century, the EU had taken over many policy areas normally reserved for sovereign states such as trade policy, agricultural policy, customs and border controls, and some aspects of higher-education policies. The creation of the European Monetary Union and the introduction of the euro in 2002 represent the highest degree of economic integration attempted so far. For the EU countries using the euro, monetary policy has been transferred from national governments to the EU removing a very significant policy instrument from the control of individual states.

This has played out quite dramatically in Greece, Spain, and other Mediterranean countries that experienced economic and financial crises in 2011–2012. In the past, these countries would have been able to devalue their currencies in order to improve their international competitiveness. As members of the monetary union, however, competitiveness can only be restored by lowering wages and profits and the policies to bring this about caused great hardship and popular unrest. Some analysts have suggested that the monetary union can only function effectively if the member states give up even more of their sovereignty by unifying fiscal policies (government spending and taxation). The EU is a regional rather than a global agreement, but its history can be taken as a guide to the broad implications of globalization. With greater degrees of integration, the world's economic resources are used more efficiently and there may be greater economic prosperity. National sovereignty, however, moves in the other direction becoming

increasingly diluted as global interdependencies increase (see Weiner 1996; Bagwell and Staiger 2004). Whether the benefits of globalization outweigh the cost of diminished national sovereignty is hotly contested (see Singer 2004; Rosset 2003; Rodrik 2011).

While international trade is only one aspect of the broader process of globalization, it has long been the object of some of the more contentious policy debates. In recent years, two sets of issues have become prominent in discussions of the relationship between international food and agricultural trade and national sovereignty. The first set relates to the idea of food sovereignty defined as the right of people to control their own food supplies in the face of an onslaught of unnatural foods promulgated by multinational firms in the globalizing world economy (Rosset 2003). The second set concerns the coordination of domestic food and agricultural policies through international organizations such as the WTO, EU, or NAFTA. In both cases, ethical claims are often made to support contrasting positions taken by the proponents and opponents of international trade and globalization.

Food Sovereignty

The problem of economic development in low-income countries became more prominent after World War II with the dismantling of colonial empires and the beginning of the cold war competition for allies. Most intellectual and strategic approaches to development fall into one of two camps. The first, based on mainstream economic thinking, sees economic relations between rich and poor countries as mutually beneficial and emphasizes the importance of trade and domestic and foreign investment. Alternative conceptions draw on Marxist thought, particularly the writings on imperialism of Lenin and Rosa Luxembourg, casting economic relations between industrialized and developing countries as exploitative. This second tradition includes dependency theories and lives on today in the modern anti-globalization movement. From these perspectives, international trade and the international organizations such as the WTO, World Bank, and International Monetary Fund (IMF) that

oversee world economic and financial systems are the primary cause of poverty in developing countries. Prior to the breakup of the Soviet Union, many governments in developing countries chose to implement socialist development strategies that included protectionist trade policies, nationalization of foreign-owned firms, and extensive government intervention in markets. In this setting, food self-sufficiency, defined as the production of most or all of the food consumed in a country within the territory of that country, was a common policy goal.

Food self-sufficiency has also been of concern in high-income food-importing countries such as Japan and Korea. In Japan, achieving self-sufficiency in the main staple food, rice, required the prevention of rice imports, and this led to domestic rice prices that were sometimes more than seven times the world price for rice of equivalent quality (Peterson 2009). From the perspective of international organizations such as the Food and Agriculture Organization (FAO), the World Bank, or the WTO, concern with food self-sufficiency has been seen as a costly mistake. The FAO favors an alternative goal, food security, defined as sufficient amounts of safe and nutritious food from domestic production and/or trade, distributed equitably and produced in a manner that is sustainable so food will be available over time (FAO 2006). For those committed to the idea that trade is just another word for exploitation, the fact that trade is treated as a means to achieving food security makes that concept unattractive. An alternative is the idea of food sovereignty suggested in 1996 by a peasant organization known as Via Campesina (Windfuhr and Jonsén 2005):

Food sovereignty is the right of peoples to define their own food and agriculture; to protect and regulate domestic agricultural production and trade in order to achieve sustainable development objectives; to determine the extent to which they want to be self-reliant; [and] to restrict the dumping of products in their markets... (see Rosset 2003 or Windfuhr and Jonsén 2005)

Those who promote food sovereignty usually suggest that the movement is not opposed to international trade, but the emphasis on local production

and consumption generally seems to support opposition to liberal trade policies. In addition, food sovereignty advocates favor the right of countries to erect protectionist trade barriers, particularly when aimed at countervailing the dumping of cheap food that undermines local producers. Most mainstream economists would agree with the argument that farm subsidies in high-income countries slow world economic growth and harm producers in developing countries by depressing world prices but would point to the benefits of the WTO in its efforts to reach agreements that limit these subsidies (Peterson 2009). In contrast, some in the food sovereignty movement call for removing food and agriculture from trade agreements such as the WTO Agriculture Agreement or NAFTA (Rosset 2003). Advocates of food sovereignty argue that food should be seen as a basic human right and that the best way to realize this right is through local food systems based on small-scale agriculture using sustainable methods. Via Campesina (2012) has called for food self-sufficiency which, if taken literally, means that international food and agricultural trade would be eliminated.

Schanbacher (2010) contrasts food security and food sovereignty, concluding that food sovereignty provides a superior framework for addressing broad global issues related to food, hunger, and poverty. To reach this conclusion, he first contrasts the two concepts from the point of view of human rights and then examines them from the perspective of the capabilities approach championed by Amartya Sen and Martha Nussbaum (see Nussbaum 2000 and Sen 2009). Schanbacher considers food to be a basic human right and argues that food security based on trade and the integration of local food systems into global markets violates this right by removing the option for individuals to decide what kinds of food they wish to produce and consume. This argument hinges on the notion that consumers will always prefer traditional, locally produced food to imported food and this may not always be the case, particularly when the local systems are incapable of producing enough calories to satisfy nutritional needs. It also requires that globalization remove the option of continuing to produce

and consume in traditional ways and this outcome is not inescapable. In terms of the capabilities approach, Schanbacher (page 106) claims that food sovereignty allows the “agrarian poor” to exercise greater control over their lives and this control is necessary for their capability to realize dignified lives (Nussbaum’s seventh central human capability, part B). Schanbacher’s discussion is based on value judgments that favor local over global, small-scale operations over larger, transnational systems and “fair trade” over “neoliberal” economic models and profit maximization.

Food sovereignty as described by advocates such as Rosset (2003) and Schanbacher (2010) is closely related to other movements advancing alternatives to the global, industrial food system, including the slow-food movement, community-supported agriculture, organic agriculture, fair trade, and those promoting local consumption (locavores). These movements usually take it as self-evident that the current world food system has failed because of widespread hunger, malnutrition, obesity, and other food-related illnesses. While they have had limited success in changing the nature of the world food system, their membership is growing and they may eventually exercise greater influence on agricultural policies. The FAO has agreed to include food sovereignty in its discussions of global food policy (FAO 2012). In the EU, measures to insure animal welfare and resistance to genetically modified food have become widespread, and many individuals in high-income countries have opted for alternative sources of food such as farmers’ markets and local food cooperatives because of beliefs that conventional foods are unhealthy or produced in ways that involve animal cruelty or that harm the environment. Aerni (2011) sees a positive role for the food sovereignty movement but points out that it “... still contains too much old left-wing ideology and too little creative thinking on how to make better use of today’s global new knowledge economy to promote sustainable development” (page 23).

Those less sympathetic to the anti-globalization and anti-capitalism tenor of much of the food movement criticisms would point out that it may not be possible to feed a world of ten

billion people with average incomes higher than today’s without modern technologies, including genetically modified food, and that such alternatives as organic food will probably never be able to account for more than a small fraction of the world’s food supply. Italy, the home of the slow-food movement, ranks tenth in the world in terms of the number (290) of McDonald’s restaurants (http://www.nationmaster.com/graph/foo_mcd_res-food-mcdonalds-restaurants), and the output of the industrialized global food system, including its fast-food industries, dominates world food production and consumption. Still the food sovereignty and other food movements have drawn attention to a range of ethical issues related to sustainability, poverty, and health as well as problems in the oversight of trade and globalization, and a rich literature has developed to address the ethical dimensions of these questions.

Agricultural Policies

The food sovereignty movement is concerned not only with the kinds of food people are able to consume and the impacts of producing this food on the natural environment but also with the well-being of the producers themselves. This concern has long been shared by governments although their interests are often less humanitarian than political. In Japan, the Liberal Democratic Party has particularly strong ties to rural voters who have often been critical in the party’s electoral success (Peterson 2009). If a government decides to isolate its country from world markets, it can establish any kind of agricultural policy it wishes as long as domestic political support is forthcoming. Once a country begins to trade with other countries, its agricultural policies can no longer be set without considering the international repercussions. The EU again provides a telling example. Prior to the establishment of the EEC, the six-member countries had independent agricultural policies supported by trade barriers that allowed differences in food and agricultural prices to persist. With the formation of the EEC, trade barriers were to be eliminated making these national agricultural policies impossible to sustain. To facilitate the transition to a common market, the member states set up the Common

Agricultural Policy (CAP) replacing the pre-existing national policies with a single set of agricultural regulations applied in all member states. The compromise that was struck when the CAP was created was to set internal prices at levels high enough to satisfy the least efficient producers in the member countries with extensive use of trade barriers applied to nonmembers to protect these high prices (Peterson 2009).

For countries that had traditionally sold large amounts of agricultural commodities to European food processors and producers, the high trade barriers set by the CAP were unwelcome. When the United Kingdom (UK) joined the EC in 1973, countries such as Australia and New Zealand that had traditionally supplied the UK market saw their export sales decline (Peterson 2009). Because of early opposition from the United States, the GATT had not included extensive provisions related to agriculture, so there was no forum for resolving disputes over agricultural trade barriers. This became critical as the EC successfully rebuilt its agricultural sector after the destruction of World War II and began not only restricting imports but also subsidizing exports of its growing surplus food production. In the 1980s, the EC and the United States engaged in a kind of subsidy war with each side trying to spend the other into submission. The favored instruments for these policy wars were various types of nontariff trade barriers. The classic barrier to trade is a tax (tariff) levied on imported goods. Under the GATT, industrial tariffs had been reduced substantially, but agricultural barriers had not been addressed. For technical reasons, the nontariff barriers deployed to protect domestic agricultural producers in the 1980s cause greater disruption of world markets than tariffs, and the widespread use of these instruments meant that world commodity markets were seriously distorted. Delegates to the Uruguay Round (1986–1994) trade negotiations elected to include agriculture for the first time in a multilateral trade agreement and with a great deal of difficulty managed to craft a set of rules on international agricultural trade that were included as part of the newly formed WTO.

Although the WTO Agriculture Agreement has not been entirely successful at reducing or eliminating farm subsidies, it has resulted in some significant changes, most notably in the EU which has eliminated its system of export subsidies and severely reduced the level of protection afforded its farmers (Peterson 2015). Based on data from the Organization for Economic Cooperation and Development (OECD 2012), 87% of producer support in 1986 in the EU was generated through trade barriers compared with only 23% in 2013. Moreover, almost half of EU support in 2013 was in the form of direct payments that are not tied to production and are judged by the WTO not to distort world markets. In contrast, only 26% of 2013 US producer support was not tied to production and these non-distorting direct payments were eliminated in the 2014 US Farm Bill. Because there are still substantial distortions in world food and agricultural markets, further negotiations on the agricultural disciplines have been conducted in the context of the Doha Development Round (DDR) launched in 2001. The DDR negotiations have progressed very slowly and the prospects for a successful round are not promising. While not the only bone of contention, conflicts over agriculture have played an important role in slowing the negotiations.

One reason why agriculture has been so contentious not only during multilateral trade negotiations at the WTO but also in regional and bilateral trade agreements such as NAFTA is that farmers are often seen as honest, hardworking individuals who are vulnerable to the vagaries of world markets and who deserve protection from foreign competitors. Much has been written about the virtues of family farms and the values thought to be promoted by an agrarian way of life (Comstock 1987; Thompson 2010). International food and agricultural trade may drive traditional farmers out of business causing them hardship and disrupting vibrant rural communities. In addition, declining agricultural sectors may mean that a country becomes dependent on foreign suppliers making it vulnerable to international political events. In 1973, US President Richard Nixon placed an embargo on US soybean exports because of rising domestic food prices. The

embargo seriously disrupted Japanese livestock industries strengthening incentives for Japanese governments to push for food self-sufficiency (Peterson 2009). Finally, the influence of agricultural groups, particularly in high-income countries, has been translated into protectionist policies that are politically difficult to dismantle.

Policies to protect uncompetitive producers, however, have negative consequences for domestic consumers and farmers in other countries. Japanese rice policies mean that consumers in Japan face rice prices much higher than the world price, and *japonica* rice farmers in California and Australia receive lower prices than would be the case if the Japanese market were opened to international trade. Low-income consumers in developing countries may benefit from low world prices, while farmers find it difficult to compete. Whether greater weight should be attached to the interests of poor consumers or to those of poor farmers is a difficult ethical question. Most economic analyses show that the gains from agricultural trade liberalization are greater than the losses and that even unilateral reduction of trade barriers will increase overall economic welfare in the country electing to reduce or eliminate its trade barriers. The problem is that the gains are generally spread thinly across large numbers of people, while the pain is often concentrated in particular groups such as subsistence farmers in low-income countries or Japanese rice growers.

In recent years, the range of issues being addressed in trade agreements has expanded far beyond traditional barriers to trade such as tariffs or export subsidies. National policies related to animal welfare, organic foods, genetically modified foods, production methods involving the use of hormones or techniques thought to be cruel to animals, and many more can actually serve as trade barriers. The US and Canadian governments have always maintained that the EU ban on imported meat from animals treated with hormones is a disguised trade barrier designed to protect EU producers from competition from lower-cost producers in North America. EU authorities counter that the real purpose of the ban is to protect consumers from potentially harmful foods invoking the precautionary

principle to justify policies restricting access to foods that have not been proven to be harmful. As in the case of the food sovereignty movement, it is often argued that trade and globalization disrupt traditional farming and food systems that have important ethical, cultural, and environmental values. But as with conventional trade barriers, protection of the traditions of one group may have negative repercussions for the well-being of other groups raising complex ethical questions.

Conclusion

Trade and globalization place constraints on the exercise of national sovereignty in all aspects of international relations including those related to food and agricultural trade. Some deplore this and argue for slowing globalization and protecting domestic agents from foreign interference. Others see declining national sovereignty as desirable because it reduces the ability of national governments to oppress their people and to interfere with voluntary economic exchanges. Ethical questions related to such issues as food sovereignty and domestic agricultural policies have been the subject of much reflection and discussion.

Introduction

States faced with behavior by foreign governments that are perceived to be objectionable have a variety of policy responses ranging from doing nothing to declaring war. Among the foreign policy tools available, various types of sanctions have frequently been deployed both by individual states and collectively through international organizations such as the United Nations (UN). Sanctions involve the suspension of normal relations with foreign countries with the aim of forcing the offending government to alter its behavior. They are often seen as more effective than diplomatic responses but less costly than outright war. Economic sanctions, the most common type of sanction, are defined by Hufbauer et al. (2007) as “. . . the deliberate, government-inspired withdrawal, or threat of withdrawal, of

customary trade or financial relations.” Governments may also initiate sanctions that are less directly related to inflicting economic harm such as travel bans or denial of educational opportunities for particular individuals. Economic sanctions are not a new policy tool. Hufbauer et al. (2007) trace their use back to the Peloponnesian War and have assembled information on 174 cases of the use of economic sanctions during the twentieth century, noting that their list is not exhaustive. Prior to 1990, economic sanctions were fairly rare and generally used as part of broader war efforts. With the end of the Cold War, economic sanctions became the foreign policy tool of choice in conflict situations giving rise to a vast literature on their effectiveness and the ethics of inflicting economic hardships on residents of offending countries (Gordon 2015; Rarick and Duchatelet 2008; Weiss 1999; Winkler 1999). The purpose of this article is to review the use, legality, effectiveness, and ethics of economic sanctions with particular reference to trade in food and agricultural products.

The Use of Trade and Other Forms of Economic Sanctions

As noted above, sanctions have been applied by individual countries as well as by groups of countries through international organizations or ad hoc coalitions. US economic sanctions against Cuba are an example of unilateral sanctions. The United States has resorted to unilateral sanctions more often than other countries, in part because it has the largest economy in the world, and the dollar is the primary international reserve currency, giving it a greater ability to inflict economic harm than is the case for many other countries (Mohamad 2015; Winkler 1999). At the same time, multilateral sanctions imposed by the United Nations Security Council and other groups of countries have become much more common. Boulden and Charron (2009) count 23 cases of UN sanctions between 1990 and 2009. Boomen (2014) notes that most of the multilateral sanctions regimes imposed during the 1990s were comprehensive covering virtually all trade and financial relations, including

food and medical supplies, between the target country and the rest of the world. The comprehensive economic sanctions that were applied to Iraq, Haiti, and Yugoslavia in the 1990s are widely seen as having devastating effects on ordinary citizens while being largely ineffective in changing the behavior of the political leadership (Heine-Ellison 2001; Cortright and Lopez 2002; Gordon 2012; Elliot 2009; Weiss 1999).

The collateral damage of comprehensive sanctions has led many to advocate for their replacement with targeted or “smart” trade and financial sanctions (Cortright and Lopez 2002; Drezner 2011; Lopez 1999). Targeted sanctions are applied to specific economic sectors (e.g., petroleum exports or military equipment imports) as well as to the individual leaders who are pursuing the objectionable policies through travel bans, freezing of personal assets held abroad, and other measures intended to force them to alter their behavior. Food and medical supplies are generally excluded from targeted sanctions on humanitarian grounds. Many analysts believe that such sanctions are likely to be more effective in bringing about a change in the offensive behavior with fewer negative humanitarian consequences (Lopez 2013; Cortright and Lopez 2002). Both targeted and comprehensive trade sanctions can be applied to exports to the target country as well as to that country’s exports to other countries. In 1980, The US government embargoed grain shipments to the Soviet Union in response to that country’s invasion of Afghanistan (USDA 1986). Since 2005, the United States and other countries have barred imports of Iranian petroleum along with other trade and financial sanctions in an effort to force Iran to comply with its commitments under the Nuclear Nonproliferation Treaty (Laub 2015). Some of these sanctions have been lifted as the Iranian government complies with the Joint Comprehensive Plan of Action to limit Iranian nuclear development to peaceful purposes adopted on July 14, 2015, by the governments of Iran, the United States, Russia, China, France, the United Kingdom, Germany, and the European Union (US Department of the Treasury 2015).

Reynolds and Wan (2012) count 143 sanctions cases during the 1990s applied to Iran, Iraq,

Libya, and North Korea mainly as efforts to prevent the development of nuclear arms. Boomen (2014) estimated a total of 500 sanctions in the 1990s deployed for a wide range of reasons. The use of sanctions increased after the fall of the Soviet Union leading some writers to refer to the 1990s as the “sanctions decade” (Lopez 2013; Boulden and Charron 2009). There are many reasons for the imposition of trade and financial sanctions. Common goals include putting an end to hostilities between two countries, protecting vulnerable populations from human rights abuses, and preventing the development of nuclear arms. In addition, sanctions may be intended to force governments to institute democratic reforms, to protect the environment, or to cease violating broad human rights norms such as the exploitation of child labor (Boulden and Charron 2009). Hufbauer et al. (2007) note that a significant motivating factor in the use of sanctions is to “demonstrate resolve.” Faced with political pressure to do something to respond to atrocities committed by foreign regimes, individual governments or the international community operating through the UN may choose to implement sanctions as a way to signal disapproval of the offensive behavior. Boomen (2014) argues that even though sanctions have generally failed to achieve their stated objectives, they have played a positive role in defining international behavioral norms.

Economic Sanctions and International Law

International law is created by states that consent to be bound by international rules (Henkin 1995). These rules primarily appear in the form of treaties or customary international law, which results from “a general and consistent practice of states followed by them from a sense of legal obligation” (Statute of the International Court of Justice, 1945, art.38(1) (b)). A state’s action is presumed to be valid unless the state is bound by a positive legal obligation to the contrary. Interestingly, economic sanctions pit the sovereign interests of the sanctioning state to act freely against those of the sanctioned state to preserve its sovereignty.

Importantly, there is no overarching treaty or customary rule prohibiting states from imposing economic sanctions (Carter 2013). To the contrary, Article 41 of the Charter of the United Nations (1945) explicitly states permits economic sanctions in certain circumstances, and the long record of state sanctions negates the possibility that customary law proscribes their use. Since economic sanctions do not violate international law *per se*, a number of scholars concerned about the efficacy and consequences of economic sanctions have argued that legal obligations arising under human rights law, international humanitarian law, or World Trade Organization (WTO) agreements should restrict states’ ability to employ sanctions. The likelihood that any of these bodies of law would limit a state’s general ability to use sanctions is, as discussed below, quite slim, which suggests a more prominent role for ethics in shaping state policy with respect to sanctions.

Human Rights Law

The contention that human rights law should restrict states’ ability to impose economic sanctions has drawn substantial attention (Joyner 2015; de Waart 2015; Bulto 2011). A state’s human rights obligations come from the treaties to which it is party and customary international law. The argument is that economic sanctions cause civilian suffering repugnant to human rights such as those to food, health, or life, which may violate the legal duties of either the sanctioning state or the sanctioned state (Joyner 2015). Holding the sanctioning state responsible is problematic, however, since states’ human rights obligations generally do not extend beyond the state’s territory or to persons over whom the state does not exercise control (Henkin 1990). States can always enter into treaties that apply extraterritorially, which would hinge a sanctioned state’s ability to prevent another state from imposing economic sanctions against it on the language of the particular treaty. For instance, in 2003 the African Commission on Human and Peoples’ Rights held that the African Charter on Human Rights includes an extraterritorial obligation not to impose economic sanctions that are excessive,

disproportionate, or indiscriminate (see also Bulto 2011). Treaties “in practice can never grant full protection against economic sanctions” since they only apply as between parties, will not shield states from UN sanctions, and often contain escape clauses that permit derogation for national security or self-preservation reasons (Van Houtte 1984–85).

Nor is a state responsible for another state’s breach of its human rights obligations (Henkin 1990). There is some ambiguity as to whether a state could be held responsible for coercing another state to violate its legal obligations. The International Law Commission (ILC 2001), for instance, posited in its Draft Articles on Responsibility of States – an illustrative, but nonlegal document – that states should be held responsible for coercing another state to breach its own obligations, but only if the state exercises direct control and knowingly causes the breach (Article 18). The high threshold for control is significant because it distinguishes the state that directs human rights violations abroad from the state that acts within its own territory, yet produces consequences that are felt abroad (Kamchibekova 2007). Extending responsibility in the latter case would “impose an impossible or disproportionate burden” on states, whose actions are immeasurably influential (Lawson 2004). It’s not entirely impossible that an economic sanction could coerce another state into violating its human rights obligations, but, as the ILC itself noted, establishing the requisite degree of control to accord international responsibility will be incredibly difficult.

International Humanitarian Law

A related argument that has garnered a fair degree of interest is that international humanitarian law, also called the “law of armed conflict” or “law of war,” should restrict states’ resort to economic sanctions – characterized as a form of warfare (Joyner 2015). This argument, too, is misguided because the law of war does not apply to economic sanctions imposed during peacetime. Rather, the law of war applies to armed conflict, governing conduct during war (*jus in bello*) and resort to force (*jus ad bellum*) (O’Brien 1981). It

should be noted that where armed conflict exists, *jus in bello* does restrict states’ use of economic sanctions, which are legitimate tactics in war. For example, sanctions imposed during armed conflict must be militarily necessary and proportional. Absent armed conflict, *jus in bello* rules are inapplicable, and the law of war will not be triggered unless, under the *jus ad bellum*, a state uses force or launches an armed attack against another state (Charter of the United Nations (1945), Art.2(4)).

Proponents of this theory face a dilemma because while the meaning of “use of force” is ambiguous, law of war experts resolutely deny that intangible, indirect means like economic sanctions – even those that severely affect civilians – constitute a use of force for the purpose of invoking *jus ad bellum*. It is for this reason that states have refrained from reacting to acts like cyber aggression with armed force: there are serious doubts as to whether harms such as these trigger the law of war (Schmitt 1999). Thus, international humanitarian law is unlikely to impose any legal restriction on states’ use of economic sanctions, except insofar as the *jus in bello* limits the use of sanctions as a means of warfare between states engaged in armed conflict. Scharfen argues that “... there is no international legislation that proscribes the initiation or conduct of economic force as is found in the many legalities prescribed for the initiation and conduct of military war” (p. 97).

WTO Agreements

More persuasive is the assertion that the General Agreement on Tariffs and Trade (GATT) and the agreements under the World Trade Organization (WTO) restrict when and how member states may impose sanctions on another of the 162 members (Carter 2013). For instance, GATT Art. I requires that member states accord other members the same favorable terms on imports. GATT Art. XXI provides notable exceptions to Art. I; however, a state may forego Art. I for essential national security reasons or to comply with UN sanctions. Member states have, indeed, relied on Art. XXI to defend their use of sanctions in the past, though a WTO dispute resolution panel has yet to hear an Art. XXI challenge (Lobsinger 2006). Thus, it is unclear whether a WTO panel

would defer to a state invoking Art. XXI to defend its use of sanctions, which Lobsinger (2006) notes may be either a blessing or a curse “in that states have neither a model nor guideline to follow when issuing sanctions; yet precisely because of this lack of clarity, states are free to do as they wish.” Given that states are reluctant to resort to WTO dispute panel decisions (Lobsinger 2006) and must overcome procedural hurdles to seek WTO dispute resolution (Bown and Pauwelyn 2014), Art. XXI guidance may not arrive for some time.

Of course, any sanction limitation imposed by the GATT or WTO agreements only applies as between member states. Those treaties do not affect a member state’s ability to sanction either a non-member state or a non-state entity. Accordingly, none of the recent sanctions aimed at non-state armed groups like terrorist organizations could be said to have violated either the GATT or WTO agreements (Carter 2013). The fact that “economic sanctions themselves are rarely, if ever, unlawful” (Carter 2013) suggests a more prominent role for ethics in altering states’ policies regarding sanctions. Rather than rest on, say, a state’s human rights obligations to decline to impose sanctions, a state might take into consideration, when choosing a course of action, the foreseeable effect on the targeted population’s human rights and, where the effect will be disproportionate, choose an alternative route on ethical grounds.

The Effectiveness of Economic Sanctions

In 1983, the Institute for International Economics (renamed the Peterson Institute for International Economics in 2006) published a comprehensive analysis of trade and financial sanctions by Hufbauer, Schott, and Elliot. New editions of this work in 1990 and 2007 have updated the analysis and added new case studies. Despite significant changes in global relations since 1983, the authors note, in the most recent edition, that their original conclusions “remain robust” (page x). Their result that sanctions have been “at least partially successful in 34 % of the cases” has been cited frequently but has received mixed support in other analyses of the effectiveness of

economic sanctions (Morgan et al. 2009; Drezner 2011; Ewing-Chow 2007). The idea that sanctions may sometimes achieve the objectives that led to their imposition runs counter to a commonly held belief that sanctions are more symbolic than effective (Hufbauer et al. 2007). Some of the most visible cases, such as the US sanctions on Cuba, are widely believed to have failed to accomplish their objectives. Askari et al. (2003) suggest that the US policy goal in recent years has shifted from containing communism to promoting a democratic transition in Cuba, and the apparent ineffectiveness of sanctions in achieving that goal seems to have led to a reassessment of the best approach to promoting democracy and human rights in that country. Cortright and Lopez (2002) argue that sanctions can only be effective if their objectives and underlying rationale are reasonable and feasible. They also suggest that sanctions are more likely to be effective if they are deployed in conjunction with other diplomatic tools as part of a strategy to encourage negotiations aimed at resolving the dispute.

Assessing the effectiveness of economic sanctions requires a clear understanding of the precise objectives being pursued and controls for other factors that might explain actual economic effects. Early (2015) suggests that sanctions have generally failed to achieve particular foreign policy objectives because they are undermined by states that refuse to observe them. Boomen (2014), Weiss (1999), and Gordon (2011) argue that comprehensive economic sanctions in the 1990s did little to change the behavior of the government authorities while having severe negative impacts on the lives of ordinary citizens in the sanctioned countries. Targeted sanctions are expected to mitigate these negative humanitarian consequences, and some have argued that they are both more effective and more humanitarian than comprehensive sanctions (Cortright and Lopez 2002; Heine-Ellison 2001; Elliot 2009). Drezner (2011), however, finds little evidence of their greater efficacy and Gordon (2011) questions their superior humanitarian impacts. It seems likely, however, that targeted sanctions will continue to be deployed as a foreign policy tool, and the recent agreement with Iran on its nuclear program seems

to demonstrate that targeted sanctions can be effective in convincing government authorities to change their policies (Katzman 2015; Laub 2015).

Whether the imposition of economic sanctions results in achieving the stated objectives or not, they often have unintended and indirect impacts that may be significant. Marks (1999) examines the negative effects of economic sanctions on public health in targeted countries, while Drury and Peksen (2014) focus on their impacts on women. Particular types of sanctions such as cutting off foreign aid have also been analyzed (Hansen and Borchgrevink 2006). Jing et al. (2003) carry out a statistical analysis of the choice between alternative sanctions instruments (trade, financial, military), while Sobel (1998) and Peksen and Son (2015) analyze the impacts of sanctions on countries' economic and political stability as reflected in the value of their currencies. It is important to note that economic sanctions are not costless for the countries that impose them. Some US sanctions that were applied to agricultural goods were widely believed to have had a negative impact on US farmers, and Rarik (2007) argues that economic sanctions have imposed substantial costs on US business.

The Ethics of Economic Sanctions

Gordon (1999) suggests that economic sanctions were seen as acts of war prior to the creation of the League of Nations when they were recast as a less harmful alternative to military action. The idea that economic sanctions are similar to war in that both are intended to cause harm to another country suggests that "just war theory" might constitute an appropriate approach to assessing the morality of implementing such sanctions (Winkler 1999). Just war theory is the ethical framework for the law of war described earlier, and, in fact, many analysts have used this theory to assess the ethics of economic sanctions (Winkler 1999; Gordon 1999; Ellis 2016; Scharfen 1995). According to just war theory, the resort to war (*jus ad bellum*) requires that a set of six principles be met including that the cause be just, that the action be proportional to the harm, that other avenues for

resolving the conflict be exhausted first, that there is some likelihood that the action will be successful, and that the action be carried out by a legitimate party that has the right intentions (Ellis 2016; Winkler 1999). Ellis argues that with some adjustments to adapt these principles to the case of sanctions, it is likely that at least some economic sanctions could be crafted to conform to the *jus ad bellum* principles.

The other part of just war theory, *jus in bello*, sets out requirements related to agreements on the types of weapons that are permissible, treatment of prisoners, and other aspects of the conduct of war. Most analysts of the ethics of economic sanctions writing from the just war perspective point to the *jus in bello* principle that a distinction be made between combatants and noncombatants with only the former seen as legitimate targets for military action. Exceptions to "noncombatant immunity" can be made based on the doctrine of double effect: sanctions could cause harm to both those responsible for the actions being contested as well as to innocent bystanders. Collateral damage that is foreseen but not intended is permissible under this standard although Ellis agrees with Michael Walzer (2006) who argued that unintended consequences are only acceptable if efforts are made to minimize the foreseen but unintended effects. Gordon (1999), Ellis (2016), and others argue that economic sanctions are generally unethical because they violate the principle of discrimination: the effects of economic sanctions often fall most heavily on those who bear no responsibility for the violation that triggered them (the "non-combatants") while leaving the political leaders who are responsible largely unharmed. Winkler (1999) recognizes this problem but argues that it may be possible to set up targeted sanctions regimes that would meet the requirement for non-combatant immunity. He notes that the distinction between combatants and innocent bystanders is the central concern and argues that there may be situations in which a military strike would be preferable because it would cause less noncombatant suffering than would broad economic sanctions.

Many authors approach the ethics of economic sanctions from more conventional ethical theories

such as utilitarianism or deontology. From a utilitarian perspective, sanctions would be judged to be ethical if the harm caused to the targeted population is less than the gain that they and others will realize if the sanctions are effective. Gordon (1999) argued that economic sanctions are unethical because they cause extensive harm while being largely ineffective. Lopez (1999) countered that Gordon's focus on the comprehensive sanctions of the 1990s is too narrow and that more finely tuned, targeted sanctions regimes that would overcome the ethical deficiencies could be crafted. Many critics of economic sanctions wrote when comprehensive sanctions were the norm and when evidence of their severe negative humanitarian impacts was becoming available. At the same time, some more recent critics also find that even targeted sanctions fail the utilitarian test (McGee 2004, 2014; Rarick and Duchatelet 2008). Gordon (1999), McGee (2014), and Rarick and Duchatelet (2008) also evaluate the use of economic sanctions from a deontological perspective concluding in Gordon's words that sanctions use "the suffering of innocents as a means of persuasion, thereby violating the Kantian principle that human beings are 'ends in themselves'" (p. 124).

Ellis (2016) notes that some authors see economic sanctions as elements of international law enforcement. She points out that enforcement requires that the action be carried out by an entity that has legitimate authority and cites several writers who do not think that states have legitimate authority extraterritorially. This would suggest that sanctions may not qualify as ethical law enforcement. Another approach to the ethics of economic sanctions would be to think of them as a duty that states may have to avoid being complicit in the atrocities committed by others (Ellis 2016). This sort of duty might arise, for example, if arms exports sold by business interests in a given country are known to be used to unjustly repress minority groups in a target country. One problem with this rationale for sanctions is that there are many goods other than weapons that may be used to oppress internal groups. Food aid, for example, has often been captured by governments and used to reward supporters and punish the opposition

making food seem like an instrument of war (*The Economist* 2010). In these circumstances, most international aid agencies seem willing to take the risk that some food intended for starving populations may be diverted to the supporters of the oppressive regime if there is some possibility that at least some food will reach the intended recipients. The alternative of cutting off all food assistance would violate the widely held belief that essential items such as food and medical supplies should not be subject to sanctions because such actions cause unacceptable harm to innocent bystanders. This review of the literature on the ethics of economic sanctions touches on some of the main themes without pretending to cover all of the finer points of the debate. There is an extensive literature on the ethics of economic sanctions and one of the main conclusions from these discussions is that food should not be included in either comprehensive or targeted sanctions. There remain many difficult questions about the ethics of economic sanctions and, as Ellis argues, further research on this topic is needed.

Trade Sanctions and Food and Agriculture

The comprehensive sanctions of the 1990s generally included prohibitions on exports of food and medical supplies raising concerns about their impact on hunger and the well-being of ordinary people living in the sanctioned country. Koc et al. (2007) show that trade sanctions in Iraq impaired food security and nutritional health particularly among the poor. In an effort to mitigate these negative impacts, the UN set up the "Oil-for-Food Program" in 1996 which allowed the Iraqi government to sell oil on the world market in exchange for food (Meyer and Califano 2006). The program lasted until the 2003 US invasion of Iraq but was plagued throughout by corruption on the part of the Iraqi regime and food exporters. Botterill and McNaughton (2008) detail the scandal surrounding the actions of AWB Limited, an Australian company participating in the program. Although the intentions of the program were good and it did succeed in improving food security

somewhat, the ability of the Iraqi regime to bypass the program stipulations may have undermined its effectiveness and compromised the authority of the UN in managing similar situations in the future (Meyer and Califano 2006).

The shift from comprehensive to targeted sanctions was intended to focus the effects of the sanctions on a country's leaders, while sparing ordinary citizens from such problems as greater food insecurity or a lack of medicines and medical equipment. In the United States, these humanitarian concerns were complemented by the economic interests of farm organizations and agribusiness firms which strongly opposed restrictions on food and agricultural export sales. During the 1970s, the US government implemented several embargos on exports of soybeans and grain in an effort to manage inflation (USDA 1986). These measures were not intended to punish foreign buyers but rather to stabilize the domestic economy. One effect of these embargoes, however, was to create the impression that the United States is an unreliable supplier, and they were strongly resented by US farmers and agricultural exporters. In the 1970s, agricultural trade between the United States and the Soviet Union was opened up and US grain exports expanded substantially. When the Soviet government invaded Afghanistan in 1980, US President Jimmy Carter placed an embargo on grain exports to the USSR. This action led to some short-term reorientation of trade as other exporters reduced sales to their more traditional clients, and increased sales to the Soviet Union and the United States shifted its exports toward its competitors' traditional markets. The overall effect of the embargo on grain prices and global export quantities was minimal (USDA 1986).

Farm organizations and agribusinesses argued, however, that the embargo was a prime example of how agricultural trade sanctions can cause serious damage to the US farm economy (House Agriculture Committee 1998). Eventually, with support from pharmaceutical companies, they succeeded in convincing political leaders to pass legislation exempting agricultural goods and medical supplies from future sanctions regimes. The Trade Sanctions Reform and Export

Enhancement Act (TSRA) adopted in 2000 required "... the President to terminate existing U.S. unilateral agricultural and medical sanctions" (Cohen 2002, p. 1). Coupled with the recognition that food and agricultural trade sanctions could create hardships for people with no responsibility for the behavior of their political leaders, support from domestic economic interests has resulted in a broad consensus that food and medicine should not be included in economic sanctions. Cumbersome regulations for food and medical exports from the United States to Cuba continue to impede trade, but, in principle, there are no longer any sanctions on exports of these goods. In recent years, the main sanction affecting trade in food and agricultural goods has been the import ban on food from various European, North American, and allied countries put in place by the Russian Federation in 2014 in retaliation for the sanctions imposed by these countries in response to the conflict in Ukraine. The ban has had fairly serious repercussions for EU food exporters but has also added to the ongoing economic crisis in the Russian Federation precipitated by falling oil prices (Leifert and Leifert 2015).

Conclusion

The use of economic sanctions increased substantially following the collapse of the Soviet Union. Some of the sanctions regimes in the 1990s were comprehensive, including food, medical supplies, and other humanitarian goods and causing widespread suffering of the civilian population. There do not appear to be any restrictions in international law that limit the application of economic sanctions, which highlights the importance of ethical considerations in decisions about their use as a foreign policy tool. The negative impacts of comprehensive sanctions coupled with deference to the economic interests of domestic farm, agribusiness, and other business groups resulted in the exemption of humanitarian goods from sanctions regimes and a movement toward targeted sanctions intended to focus the harm on those responsible for the objectionable behavior. There is no clear consensus on either the effectiveness or the

ethics of targeted sanctions, although there is broad agreement that comprehensive sanctions including restrictions on trade of humanitarian goods are neither ethical nor effective. The importance of food and agricultural goods for human well-being has played an important role in the evolution of global practices with respect to the use of economic sanctions as a foreign policy tool.

Food and Agriculture in Bangladesh

Agricultural ethics and policies; Food security; Population growth

Introduction

Bangladesh is one of the most densely populated countries in the world. With extremely low per capita land, feeding its growing population has always been a big challenge. Simultaneously agricultural land uses have changed continuously and that in a way demonstrates the dynamic and complex interplays of ethical dimensions of socioeconomic, political, and technological forces (Khan and Shah 2011).

However, the rapid agricultural land use changes occurred during the last three decades mostly due to unplanned and uncontrolled urbanization and industrialization. This changing pattern of land uses has serious implications for the agriculture and food security of the country. In 1980, there were 9.0 million hectares of available agricultural land, while in 2012 it decreased to 6.0 million (Rashid 2012). It is important to note that in 1980 the country's population was approximately 80 million and currently that is reported as 161 million (Wikipedia 2013; CIA 2013). The status of food and agriculture is exposed to huge risks and so from the food security perspective. Recently, the country's environmental minister mentions that "declining farmlands and rising population were the two major concerns for Bangladesh, not the impact of climate change" (Rashid 2012). This tells how food and agriculture are critically important to the country, rather than the popular belief of climate change damages.

The government prepared the "National Land Use Policy 2001" largely as a response to this dynamic socio-environmental challenge. The policy was aimed to ensure the competitive use of land resources for food production, housing, as well as protecting the country's environment. However, as governance and policy implementation have always been issues for Bangladesh, many people therefore were always very skeptic about the implementation of this plan. This type of uncertainty at the structural level is definitely detrimental to the country's capacity for food and agricultural production for its growing population.

Recent inventory highlights that land use changes in the recent years have adversely impacted the annual rice production by decreasing

approximately 0.86–1.16% of the country's total rice production (Rashid 2012). In a land-constrained country, it is a huge issue for Bangladesh, and therefore, the country has no way without imposing strictly any resource management regulations and zoning to secure agricultural lands. Apart from this, population control, rural farm and nonfarm employment creations, further efforts to increase land productivity through the adoption of modern green technologies, uninterrupted electricity supply to the irrigation equipment, agricultural credits, and subsidy all play important roles for the sustainable food and agricultural practice in Bangladesh. The government should take the lead role in ensuring a balanced interaction between human and nature. However, in this framework, citizens' awareness and involvements are critically important.

As a populous country in the developing regions, Bangladesh has a number of developmental challenges. Nevertheless, the country has made substantial progress on several global development indicators, such as reduction of poverty or gender equality. But still malnutrition or hunger in remote areas is at an alarming level. Productive capacity of agricultural lands is still comparatively low than many of the neighboring countries and still the country is dependent on food export for its own food security (ACDI/VOCA 2011). Therefore, the commodity price increase can impact the country badly. Like any other countries, the problems of food safety and security, animal welfare and production, technological change, agricultural production techniques, pollution and environmental sustainability, and corruption of regulators and policy makers are at the core of food and agricultural ethics (James 2003).

This entry on food and agriculture in Bangladesh is divided into three major parts: firstly, after having a brief theoretical discussion, it addresses the ethical challenges of food and agriculture in Bangladesh. Secondly, this entry focuses on how the discussions of food and agricultural ethics are integrated into the local practices and contexts. Finally, it attempts to propose some policy solutions. Overall, it is expected that the discussions on this entry will generate further intellectual contributions and discussions on the ethics

of food and agricultural production in a country-specific context, where the mentioned issues are unfortunately under-prioritized in the domain of policy making and implementation.

Agriculture, Environment, and Ethics

The publication of Rachel Carson's "Silent Spring" in 1962 was one of the major turning points when the scholars started to put further insights on the discussions of agriculture and environment at large. The arguments came into front that the conventional agricultural practice could be detrimental to the environment as well as public health and safety. Some also started to investigate that the adopted agricultural practice might not be sustainable in the long run. However, this is now clearly evident that conventional or even modernized agricultural practice involves heavily the replacement of natural ecosystems as well as reason for ground-water pollution, depletion, soil erosion and degradation, and pesticide pollution along with some other associated environmental stresses and risks (Chrispeels and Mandoli 2003). Therefore, a new paradigm of food production and agricultural practice was inevitable. At the same time, the world as a whole needs more feed, more clear water, better foods with more nutrients, and substantial ecological modernization for ensuring agriculture with less environmental footprints.

All these issues together gave importance for intellectual discourse and policy implications for food and agricultural ethics. Ethics is about choices, and food and agricultural ethics is about the choices and moral components for the people, who are engaged in agriculture either directly as the producer of it (e.g., farmers) or indirectly as the consumers of it (e.g., citizens) (Chrispeels and Mandoli 2003).

In this context, FAO (2001) stresses that the world needs more equitable ethically grounded food and agriculture involving three major global development agenda, such as improved well-being, protection of the environment, and improved public health. For many countries in the developing regions, poverty is the single most issue. However, it has been proved that ethical food and agricultural

practice can ensure poverty reduction by enhancing economic and social efficiency along with the eradication of poverty, hunger, and malnutrition. Apart from that, FAO focuses on the protection of the environment and improved public health and safety, because these two are closely intertwined with the issues of food and agricultural ethics as well as involve the core components of global development.

Local Challenges

Bangladesh is relatively a small country with a total land area of 143,998 km², however with a population of 161,083,804 (CIA 2013). It is one of the densest nations in the world. Apart from other developmental challenges, the country faces challenges from limited lands for food and agricultural production for its vast population. It generates further concerns for the country's ethical positions and practices in food and agriculture. The World Bank Data (2013) reports that during the recent past, the amount of arable lands (in hectares per person) in Bangladesh has decreased in an alarming rate (Fig. 1).

In the present context of available arable lands, now in Bangladesh, there is almost no chance for horizontal expansion or growth for agricultural production; rather the country is following the trajectories with vertical growth. The current

Food and Agriculture in Bangladesh, Fig. 1 Arable lands (hectares per person)

Food and Agriculture in Bangladesh, Table 1 Basic features of land and population

Land/population	Amount
Total area (in km ²)	143,998
Land (in km ²)	130,168
Water (in km ²)	13,830
Population (July 2012 est)	161,083,804
Agricultural lands (km ²)	91,490
Arable lands (in %)	55.39
Permanent crops (in %)	3.08
Other crops (in %)	41.53
Irrigated land (in km ²)	50,500

features of land and population (Table 1), mentioned by CIA World Factbook (2013), also support that argument.

For agriculture intensification or vertical growth, usually people use pesticides and different mechanisms which often contradict with the norms of food and agricultural ethics. However, apart from this, the numbers of natural disasters also cause huge challenges to local food and agricultural chains. Almost in every year floods or the increasing impacts by the climate change, such as increased frequency of tropical cyclones, cause huge loss of crops and cropland devastations. Seasonal and sometimes unpredictable monsoon rains and floods always create further stress on local agriculture and food systems.

The consumption pattern sometimes might be a linear function of any particular group of population when technology and lifestyle are given. However, for various internal and external reasons, the environmental stress and burden are distinctively nonlinear and unpredictable in most of the cases. It has been already mentioned that in Bangladesh the population pressure has tremendous impacts on the sustainability and ethical dimensions of food and agricultural development. Further population will intensify the crisis along with irreversible damages of food and agriculture. Numbers of predictions say that in the foreseeable near future, climate change will be hard felt in this densely populated country where a substantial portion of land areas are barely above mean sea level (Mahtab and Karim 1992). It is now projected that 25–30% of the land might be lost due to the sea-level rise and that says Bangladesh will

lose its vast amount of prime agricultural lands. Already the country has started to experience salinization in land and water, particularly in southern Bangladesh. It is important to say that in the near future it will not be a surprise if climate events become the crucial determinant of the country's food and agricultural production. Bangladesh also experiences continuous erosion of its riverbanks and often that costs huge loss of agricultural lands. All these together illustrate that the country is heading towards critical ethical challenges regarding food and agriculture and subsequent human security issues, particularly when the populations are largely poor and have limited capacities to confront any types of challenges.

Theory and Practice: Food and Agricultural Ethics in Bangladesh

The country needs to feed its burgeoning population. A constant increase in demand will make increasing pressure on available lands, food, and agricultural practice. Contemporary division of human and nature in many developing countries demonstrates the mismatch between the food supplies and human nutritional needs. Unpredictable impacts of agribusiness on rural employments and consequences of modernization of agriculture on human and animal welfares along with the end effect of intensification of production systems on sustainability are some of the major reasons why agricultural and food production have become part of moral and/or ethical concerns at large (Grimm 2006).

It has been often argued that the intensification of production system has contributed to feed the country's massively growing population with nominal imports. However, at the same time this form of agricultural development has usually large environmental footprints, such as in the form of land degradation, increasing salinization in soil and water, desertification, and the increase of agrochemicals into the larger food chains. Apart from that, intensification of production system has another human dimension of the issues. It can contribute to further marginalization of poor and landless farmers. In Bangladesh often intensification of the production system happens at the

expense of a number of social costs such as increasing poverty, food insecurity, and rural unemployment.

Thompson identified some of the core premises of food and agriculture, such as (a) agriculture and agriculture communities are embedded in complex “eco-social hybrid systems”; (b) even though often agriculture and food are viewed as an economic function, but beyond producing food and fiber, they have important social functions; (c) agriculture and agricultural practices are inherently linked to environment and generate environmental footprints; and (d) finally, the ideological discourse of “pristine nature” and “ecological footprints” often generates a confrontational situation between human and nature, whereas agriculture makes a bridge between everyday life (nonspatial factors) and known places (spatial factors) (Epp 2012). To elaborate these premises in the Bangladesh context, clearly food and agriculture and the people who are closely engaged are embedded in complex eco-social hybrid systems; in other words, it is a coupled human and natural system. People are engaged in production, distribution, and consumption in the entire cycle of food and agriculture, and therefore, the entire cycle of food and agriculture has clear human dimensions. However, in doing that, both food production and agricultural practice inherently generate ecological footprints, which is again detrimental for human health or sustainable existence. Some might argue that intensification of production can reflect the core ethos of ecological modernization; however, no one can ignore the associated environmental costs.

The core ethical issue of food and agriculture in Bangladesh mostly emerged due to the country’s position on vertical production intensification. This type of production requires intensive use of chemical fertilizer. Recent estimations demonstrate that Bangladesh uses the highest amount of fertilizer per hectare in South Asia. Fertilizer consumption in the recent years, calculated from the World Bank Data (2013), demonstrates (Fig. 2) that from 2008 fertilizer consumption per hectare of arable lands has dramatically increased.

Food and Agriculture in Bangladesh, Fig. 2 Fertilizer consumption (kilograms per hectare of arable land)

This alarming rate of the fertilizer use contributes to multiple challenges, such as issues with food quality, soil quality for agricultural production, diminishing soil productivity, and raising costs for agricultural production for particularly the marginal farmers. More precisely, the excessive and uncontrolled use of pesticides might cause (a) substantial health problems among the farmers or other associated workers, (b) natural ecosystems can be exposed to severe pollution risks, (c) loss of insect biodiversity in the entire agro-ecosystems, (d) creation of unnecessary secondary pests, and (e) insects can be resistant to pesticides. All these together can pose serious questions to the ethical dimensions of food and agriculture in Bangladesh.

“Water” can be another deciding factor in this entire discourse and policy implications. Almost half of the cropland in Bangladesh is under irrigation. Currently, water is becoming a limiting factor for the sound agricultural practice in the country, most due to the increased intensification of agricultural productions and diversion of water to the non-agricultural uses (Khan and Shah 2011). In addition to that, groundwater level is decreasing for the excessive use, mostly for fulfilling the demands of large population, and at the same time for the excessive use of chemicals, the groundwater is experiencing issues like arsenic contamination.

Right now in Bangladesh prime agricultural lands are already used for agricultural production for feeding the vast population of the country. To meet further demands, expansion of croplands is

now taking place at the cost of damaging forest and other marginal lands. Apart from that, forestlands and marginal lands are also being impacted by the uncontrolled industrialization as well as urbanization. This not only will pose questions for the ethical practices of agricultural and food production but also will make enormous environmental footprints, which can be detrimental for the country and its citizens in the short and long run. Illiteracy and inadequate knowledge of sustainable agriculture are also among the major issues in the discussions of food and agricultural ethics. This would not be a surprise if the prime agricultural lands are impacted by local agricultural practices. Criticisms already highlight that large areas of South Asian countries are losing the valuable topsoil or other forms of degradation due to the poor agricultural practices (Khan and Shah 2011).

It is important to note that intensification of agricultural production and production methods have both the negative and positive impacts. This is obviously true that intensification of agriculture helped to feed the country's burgeoning population. It helped a large portion of population come out of poverty and hunger, contributed to rural economic growth, as well as contributed to save forestlands, wetlands, and other fragile ecosystems in the country from the conversion to cropland or other nonfarm uses. However, while making these mentionable important contributions, it was detrimental to genetic diversity as well as biodiversity. In addition to that, now agricultural practice is unaffordable for the marginalized farmers. In many places marginalized farmers are even poorer and shifting from farm to nonfarm practices is now quite evident. Farmers often report that they are experiencing diminishing return of agricultural productivity from their agricultural lands. The question might arise: what would be next after destroying the environment and agricultural base? And how will the country feed its vast population? All these questions and concerns therefore create an important base for the ethical practice of food and agriculture in the country. Therefore, the next challenges would be to identify how to manage this entire socio-ecological dynamics for a sustainable agricultural production in this

resource-constrained country. As a reply to these critically important and intertwined issues, "ethics" or "ethical practice" might be at the center of scientific discourse and policy implications.

Summary

Because the issues with food and agriculture are linked with poverty, hunger, malnutrition, employment opportunities, etc., it is therefore critically important to understand the ethical dimensions of eco-social hybrid system. To feed the growing population, countries like Bangladesh have adopted intentionally and/or unintentionally a number of unethical food and agricultural practices. Now it is the time to turn around and set paths towards the ethical practice of food and agricultural production. Climate change impacts will pose further challenges to the existing food and agricultural practice in the country.

However, changing direction to the ethical practice is more than agricultural modernization. Social transitions are now apparent in every corner of the world. The use of social capital and social innovations for more desired food and agricultural practice is therefore inevitable. This should contribute to manage resources more efficiently and more precisely help to sustain with increasing food and agricultural productivity. There should be more investment in research and development for ensuring the ethical dimensions of food and agriculture. In this regard, some of the following agenda can be addressed for building more equitable and ethical food and agriculture system in Bangladesh:

- (a) there should be a holistic approach in formulating environmentally sensitive and ethical plans for national land use plans and policies;
- (b) there should be adequate research and development investment to ensure continuous inventions for natural resource conservation and more particularly for ethical food and agricultural production;
- (c) the research and development efforts should be coordinated and concerted as well as should be aligned with national development policies;

- (d) as Bangladesh is a water-constrained country, there should be long-term integrated watershed management plans and strategies;
- (e) farmers should get sufficient information and training for ethical production of food and agriculture; and
- (f) building awareness and local-level capacity on the environment as well as ethical dimensions of food and agricultural production.

Above all, as in Bangladesh good governance is always a big issue; therefore, the government should ensure peoples' awareness and involvement in national land use plans, and when necessary they should pursue for revision of the plans as well. Bangladesh should take care of the ethical dimensions of food and agricultural production, unless the country might need to pay a huge price with the expenses of enormous damage and loss, when the country is already challenged by climate change and huge population in a resource-constrained environment.

Food and Choice

Erinn Gilson
University of North Florida, Jacksonville, FL, USA

Synonyms

Consumer choice; Control and autonomy; Diversity and variety; Freedom to choose; Options

Introduction

Food is understood to be a site of choice in myriad ways (Marshall 1995). Most obviously, individuals choose what food to eat. This seemingly simple choice gives rise to a variety of other opportunities for choice. One may choose to eat healthfully or not, to endorse a particular conception of what “healthful” means, to eat animal products or not, to seek the most affordable options, to select organic produce, to shop at farmers’ markets or join a CSA, to grow one’s own food, to dine out at numerous different kinds of restaurants, to eat only raw food, to buy in bulk, to avoid sugar or wheat or artificial sweeteners, and so on. Yet, choices about what to eat are never just choices about the content of what to put into one’s body. Rather, these choices are ones that reflect priorities, values, self-conceptions, and bodily needs and wants, as well as the various socioeconomic, historical, cultural, and political conditions that shape these things. When one chooses what to eat, one may also regard oneself as choosing where and how this food is produced, who is producing it, what kinds of lifestyle one aims to lead, what kind of person one aims to be, what kind of body and physical appearance one seeks to have, what kinds of communities one wishes to join, and even what kind of world one aspires to inhabit.

Choice is often represented as something that individuals ought to value in itself when it comes to food and thus as something that ought to be desired, pursued, cultivated, and encouraged both via policy and individual action. Accordingly, the value of choice in relation to food is advocated in various ways by individuals, advertisers, activists, corporations, and the media, among others. Increased variety and choice is commonly presented as a merit of a global, industrialized food system, yet myriad choices are simultaneously obscured and restricted by that same system. Thus, choice is also the mantra of those seeking to challenge the industrial food system, who contend that *real* choices – that is, meaningful choices – lie outside of that system.

Since food choices are not simply choices about what to eat and the very idea of choice is

ascribed value, it is instructive to examine the nature of the kinds of choices about food that are deemed significant and the context in which they are or become significant. Specifically, it is crucial to interrogate the assumption that the globalized, industrialized food system dramatically enhances choice, by asking the following: What kinds of choices does this system make possible? What kinds of choices does it preclude? How does it narrow or limit choices? For whom are these choices made possible and who is hampered in making them? What kinds of choices does it make visible and what kinds of choices does it obscure? Is the rhetorical claim that a globalized, industrialized food system is the only kind of system that maximizes choice, and so is best suited to Western sensibilities and preferences, valid? All of these questions cannot be addressed fully in this brief entry, so it proceeds by assessing various perspectives on the impact of the industrialized system on food choices and then considering how choice is understood in relation to this system, the dominant one that supplies food (i.e., what choice is *about* and why choice is thought to be significant).

The Contemporary Food System and Food Choice

It is readily acknowledged that the global industrial food system far expands the options available to consumers. A wide array of different types of food products is now available in supermarket chains, including types of produce and grains that previously remained regional crops (for instance, foods such as quinoa, goji berries, and acai are now fairly common in the USA, and US fast-food chains are now common throughout the rest of the world); a diversity of different kinds of retailers (ranging from supermarkets to club stores to natural food markets and so on) procure and distribute said products; fresh produce of all varieties is accessible to many year round and processed food products of all kinds have proliferated.

These developments in the amount, variety, and accessibility of food both within nations and internationally have dramatically increased

consumers' ability to make choices about how to feed themselves, including the choices of what to eat, how much time and energy to spend preparing food, and where to buy food and how much to spend on it. This increase in choice has obviously benefitted consumers, enabling them, for instance, to save money because of the advent of mega-retailers like Wal-Mart (Hausman and Leibtag 2007) and to save time because of the preponderance of convenience foods and restaurant options.

More significantly, however, the proliferation of options made possible by agricultural modernization and industrialization enables consumers to choose schemes of food purchasing, preparation, and consumption that fit best with their life-plans. From a liberal individualist perspective, the ability to maximize choice in this way is a basic good because it allows each individual or each family unit not only to determine what foods they wish to consume but also what place food has in their conception of the good life in general (e.g., one can make food central to the good life by choosing to devote the time to preparing gourmet meals with exotic ingredients or one can regard food as sustenance or best prepared by others by choosing to eat takeout meals daily).

The consequence of the global market in food is that few foods remain purely local products but rather become available as a demand for their export arises. The globalization of food distribution enhances choice in terms of an increase in variety (especially for those in Western, "developed" parts of the world) but also has adverse consequences for those whose subsistence crops become in demand for export (e.g., quinoa) (Philpott 2013). Thus, the expansion of options and increase in variety that might be said to characterize the global food system is far from equitable and might even be described as distributing inequity. Imports into Western, "developed" parts of the world tend to be items desired for their health benefits whereas imports from the West into "developing" parts of the world tend to be far from healthy, highly processed food products, including items such as enriched bread and fast food; moreover, poverty and inequity of access *within* industrialized countries entails that increased variety benefits the middle and upper

classes to a far greater extent than it does the lower classes. Problems of access such as food deserts limit the choices of the poor, but they are also simply priced out of the markets for healthy, organic foods (Winne 2008, p. 177). Thus, Mark Winne contends that "[w]e have in America today a tale of two food systems – one for the poor and one for everyone else" (2008, p. 175).

Whereas Winne's criticism of the burgeoning market for organic, humanely raised, fair trade, local, and "green" food highlights the way choice is a privilege afforded by wealth and the focus on sustaining farmers eclipses concerns about the poor, others focus on the way the decisions and forces that lead to increased consumer choice often constrain the choices available to farmers, consigning them to poverty, debt, and sometimes suicide. Consumer freedom and choice, especially as it pertains to price, are often invoked as a rationalization for low wages for farmers and workers and for centralization and market concentration. Raj Patel illustrates this point with the case of Ugandan coffee growers: When coffee prices drop in a globalized market, growers who have land suited to little else besides growing coffee find themselves compelled to grow more to earn enough to survive but doing so creates a surplus and drops the commodity's price further.

With the milling, roasting, exporting, and transporting in the hands of multinational corporations like Nestlé, coffee growers lack control over their crop and its price. While growers may be paid 14 cents per kilo of coffee, after processing the price rises to "US \$26.40 per kilo, or nearly 200 times the cost of a kilo in Uganda" (Patel 2007, pp. 9–10). Centralization and market concentration disempower farmers even as it may enable corporations to present more options to consumers; thus "our choices at the checkout take away the choices of those who grow our food" (Patel 2007, p. 8). The creation of "food chain clusters" – both vertical and horizontal integration – allows major corporate players (such as Cargill, Monsanto, Archer Daniels Midland, Smithfield, and ConAgra) to control the production of a food from seed to manufacturing and shift decision-making from farmers to corporate offices (Hendrickson and James 2005).

Moreover, as Hendrickson and James contend, this shift in power and control results in diminished and constrained choice for farmers, which leads to both a loss of farmers' knowledge and skills and "an erosion of farmer ethics" (Hendrickson and James 2005, pp. 278–279, 285). By altering the self-identity of farmers, agricultural industrialization and the ensuing constraints on choice can make agriculture "a place where ethically compromised positions could become natural for farmers" (Hendrickson and James 2005, p. 289). Overall, therefore, choices about what to eat may be increased for some, but these choices are both inequitably distributed along the lines of socioeconomic class and premissed on impeding others' choices.

Another counterpoint to the view that the global industrial food system increases the options available to consumers is the fact that actual diversity in both crops and diet has decreased dramatically. Though some critics focus on the effect of agriculture on biodiversity (Cafaro et al. 2006), others focus on the way industrial production, exemplified by monocultures, has led to a loss of diversity in the plant and animal species in agriculture (agrobiodiversity) and thus in diet. The Food and Agriculture Organization of United Nations estimates that "75 % of plant genetic diversity has been lost" since the 1900s (Economic and Social Development Department of the Food and Agriculture Organization 2004) with the consequence that "[m]odern U.S. consumers now get to taste less than 1% of the vegetable varieties that were grown here a century ago" (Kingsolver 2007, p. 49).

The exigencies of a global and industrial system demand that plant cultivar are selected for a select set of characteristics that are conducive to mass production, transport, storage, and supermarket presentation; thus, ease of harvesting, resistance to bruising and spoiling, uniformity in appearance, and so on are the criteria that determine both which cultivar consumers will find in supermarkets and how these cultivar will be bred and/or genetically engineered. So, consumers will not find apple varieties like the "Calville Blanc, Black Oxford, Zabergau Reinette, Kandil Sinap or the ancient and venerable Rambo on the shelves"

(Patel, p. 2). Nor is it likely that the majority of consumers have heard of these varieties; thus it is unlikely that they realize that their choices have been restricted in advance. Corporate concerns about expediency, efficiency, and profit circumscribe the choices that consumers make in the store. Thus, the variables over which consumers may exercise control and make choices are de facto limited: "[w]e may choose between varieties, but not their presentation or the overall selection of goods on offer. When it comes to product quality, safety, and ethics we have to rely on liability and truth-telling" (Kjaernes 2012, p. 152).

A related concern is the decline in diversity in diet: Three crops – corn, wheat, and rice – comprise 60% of the human diet (Economic and Social Development Department of the Food and Agriculture Organization 2004). In the USA, 75% of the average person's diet is comprised of eight species (Kingsolver, p. 49) and two thirds of this diet is corn, soy, rice, and wheat (Pollan 2008, p. 117). Since agrobiodiversity is increasingly correlated positively with health and food security, especially for rural populations, this reduction in diversity is significant (Johns and Eyzaguirre 2006; Nicklas et al. 2001; Thrupp 2000). Thus, the availability of innumerable food products does not translate into dietary diversity; the presence of options does not necessarily lead consumers to take them up. In this way, the kind of choice the system proffers is just the presence of options and the mere possibility of taking them up.

The narrow array of foods that comprise the average US diet is intertwined with yet another concern about the way choice is manifest in a global, industrialized food system. Critics of the impact that this system has had on the health of consumers point out that many of the products available are simply reconfigurations of the same basic components, especially including the aforementioned soy, corn, wheat, and rice as well as sugar, fat, and salt. The number of food products available in US supermarkets has increased from approximately 4000 in the 1950s to an average of 38,718 in 2010 (FMI: The Voice of Food Retail 2012). The number of new products introduced is

even more dramatic: “18,722 new food and beverage products were introduced in 2005 alone. . . [however,] many ‘new’ products turned out to be simply adaptations of existing products (‘Oreos with a different color icing,’ as one food product development researcher put it), . . . [with most] disappearing after a couple of years” (Gottlieb and Joshi 2010, p. 51).

The proliferation of new products aims to entice consumers to buy, and thus the main focus is on altering the packaging, branding, and messages coupled with the food product in order to attract consumers (Gottlieb and Joshi, p. 45). For such marketing to have its desired effect, though, it must portray the products as presenting genuine choices; such choices are often less about the content of product and more about the image associated with it. In the case of many cereals or soda, the diverse products are often simply different configurations of sugar or artificial sweeteners and so the choice is no longer one about food *per se* but about image and message. Advertising campaigns still play on the ideal of choice, however, as when the Coca-Cola beverage company markets its low- and zero-calorie beverages (including bottled water) as “healthy options” in order to establish the company as enabling meaningful (i.e., health-related) choice. Yet critics conclude that this depiction of choice is basically an illusion; given the minute differences in the products and the ultimate insignificance of the choice, “the choice between Coke and Pepsi is a pop freedom – it’s choice lite” (Patel, p. 17).

Choice and Alternatives to the System

Various alternatives have arisen in response to the ethical and ecological problems inherent in industrial agriculture and the health effects of the kinds of food that are its major product. Alternatives include foods that are labeled, marketed, and/or certified as organic, sustainable, humanely raised, fair trade, nongenetically modified organisms (GMO), local, or “green” zero-emission products. In various ways and to varying extents, these alternatives constitute resistance to the ecologically devastating, inhumane, and unhealthy

methods characteristic of global industrial agriculture and food production. Accordingly, the ideal of choice is crucial for such alternatives since they are often understood as, and/or marketed as, offering choices that either are not contained within or are precluded by the industrial system. In particular, these options appeal to the idea that our food choices signify more than a concern about the content of the food product.

Choices about food are choices about ethics, including how animals, human beings working in agriculture, and the environment are treated. In many cases, alternatives to the industrial system require eaters to see the kinds of choices presented within that system as illusory, as “choice lite,” and so to understand the choices presented by the alternatives as more meaningful choices. The meaningfulness of these choices lies in the way in which they involve a more expansive sense of the implications of food production and consumption. In choosing what beverage to drink, one is doing more than choosing between a drink with calories and one without calories or between one in a blue can and one in a red can; one is choosing whether the farmers growing the coffee beans are paid a living wage or are barely subsisting, whether the coffee is grown in a sustainable manner or in a way that caused deforestation, and so on. In this context of a rise in ethical consumption, the concomitant desire of individuals to know more about their food in order to make informed choices, and the increasing sense that food choices reflect on who people are, Tavernier argues that consumers have a right to know about food production methods and the ecological impact of their food (Tavernier 2012; Beekman 2008). Along these lines, Coff suggests that the “ethical traceability” enables more informed food choice because it “can address the ethical, as well as the practical and physical, aspects of” the history of a food (Coff et al. 2008, p. 1).

Despite the increasing array of more ethical choices on offer, there is some concern and skepticism about their meaningfulness and about the value of the information provided through standard means such as labeling and certification. Labels like “organic” and “non-GMO” are often adopted by the very mega food corporations to

which alternatives are sought (Kastel 2006). The same large corporations frequently buy out smaller organic or natural brands, which thwarts attempts to redirect consumer support (Howard 2009; Johnston et al. 2009). Substantive changes in agricultural and production practices do not necessarily follow, however (Guthman 2004). Consequently, the significant social differences – in working conditions and wages, in the scale of production and its associated effects on soil erosion, and in the connection consumers do or do not feel to their food and those who grow it – can be virtually nil.

Moreover, as Roff contends, the ethical consumption movement's emphasis on individual "freedom of choice" "vests responsibility in the individual and focuses attention on consumption as the new arena of citizenship[.]" obscuring the inequitable distribution of the ability to choose and the structural and political nature of responsibility (2007, p. 515; see also Bakker and Dagevos 2012 in support of the idea that citizenship can be effectively exercised through consumer choices). Aspiring to greater consumer "freedom of choice" does not require one to question the current high levels of consumption and their ecological impact and, further, can be achieved through similar kinds of reconfigurations of familiar foods, including highly processed products (Roff 2007, p. 517). Likewise, Kjaernes notes the limits of labeling schemes to address ethical concerns about industrial agriculture and food production; although labeling constitutes an attempt at transparency and the provision of more information, such schemes require competence in reading labels and trust that the labels mean what they say, and may simply comprise a means for corporations to increase profit (Kjaernes, p. 157). Moreover, labels may provide consumers with a degree of expanded choice but "if people's concerns and critique are directed towards the lack of personal interaction and direct control, then ethical labels and assurance programs cannot resolve that" (Kjaernes, p. 153).

Additionally, the question of whether mandatory labeling really maximizes consumer choice is itself a point of debate (Carter and Gruère 2003; Siipi and Uusitalo 2011). Busch summarizes the

problem as "the private governance of food[.]" which while it "permits and even stimulates some forms of (more) equitable exchange, it also creates a bizarre bazaar where goods are differentiated by a growing and often bewildering array of standards, most of which are only made visible to consumers through claims embodied in certifications" (2011, p. 351). The labels, certifications, and other assorted claims about food products provide "greater choice to consumers even as it makes choice into a burden" (2011, p. 351). Thus, as Wilkins notes, the most genuine *alternative* to the industrial food system may be found "by shopping outside the mainstream food system – buying at least some food at a farmers market or roadside stand, or joining a CSA" (2005, p. 271). The most significant way to increase choice is likely to extricate oneself from the mainstream food system as much as possible.

Summary

If choice is valued both from within the conventional food system and by those who challenge it, then it is worth considering why choice is regarded as significant and where its value is thought to lie. On the one hand, choice is understood simply as having options from which to choose; that is, choice is valued because it is defined in terms of the presence of variety and the freedom to select what is most desirable or best suited to one's needs from that variety. The nature of these options may vary considerably, ranging from a selection of products that are essentially different configurations of the same basic ingredients (differing primarily in their packaging and marketing) to having options whose content is significantly different (for instance, processed food products versus unprocessed, "natural" foods) to foods that are chosen not solely because of their content but also because of the implications of the practices involved in their production.

Although consumers choose from different types of food, they might choose a given option because of other variables: By choosing fair trade, consumers may seek to impact wages and working conditions; by choosing humanely raised

animal products or not to eat animal products at all, consumers may seek to impact the welfare of animals; by choosing zero-emission products, consumer may seek to minimize the contribution their purchases make to climate change, and so on. Thus, on the other hand, the meaning of choice also extends beyond simply having options (being able to choose, for instance, from among ten different items rather than just three) to being able to make an impact on the processes and systems that are related to one's consumption. One's choice is not just whether to buy organic or not but is also a choice about the use of pesticides, contribution to soil erosion, and so on. The meaning of choice thus also lies in being able to exercise some control over the significant variables – methods of production, working conditions, environmental impact, quality and safety of the food product, etc. – that are involved in the choice rather than abdicating this control to other parties.

Both senses of choice are intrinsically connected to freedom, autonomy, and the ability to engage in self-determining action. To the extent that an ideal of choice is part of how food is marketed, food corporations focus on the first dimension of choice: the presence of variety and the freedom to select from these options, which easily becomes “choice lite.” From the perspective of players in the global, industrial food system, the second dimension of choice – exercising some control over the significant variables related to one's food – is subsumed under the first: Control is to be found in selecting from the options the industry affords consumers. Since food corporations need to retain control over their methods of production, among other things, the degree of control available to consumers is just the control over which item they select. Thus, the choice between the available options must be construed as a significant and meaningful one, as a choice that says something about one's self-conception, for instance (Bordo 1999).

On some accounts, the proliferation of variety and the need to choose from an increasingly wide assortment of items can even create anxiety as consumers are encouraged to regard each choice as meaningful (Schwartz 2004; Salecl 2010). Thus, those who criticize and challenge the

industrial system work to reveal these choices as basically chimerical, as far less important than they are depicted, and as tied to the disenfranchisement of others. In contrast, they emphasize the importance of control over the significant variables related to one's food, variables that impact the overall health and well-being of humans, animals, and the environment. They also emphasize the difference between a cognizant choice and an unwitting choice. In a landscape in which choices are commonly molded and manipulated to varying degrees, reacquiring control over how, where, and by whom food is produced, processed, transported, and sold requires an understanding of the way choices are shaped.

The difference between cognizant choice and unwitting choice is thus also a difference between understanding *that* choices are shaped (rather than being pure expressions of desire) and how they are so, and the absence of this critical awareness; such critical awareness also involves recognizing the way in which an idea or image of choice is a central part of how food products are marketed to consumers. These forms of awareness are considered central to regaining control over something as vital as food and reestablishing the full value of choice. Thus, alternative food systems seek to restore the meaning of choice by emphasizing both dimensions of choice equally and advocating for the idea that genuine variety and the freedom to choose only arise in the presence of decentralized, democratic control over the significant variables involved in food production and consumption.

Introduction

The act of eating, while simply defined as the consumption of food, has many social and cultural factors tied to it. These factors include how societies define what is edible or not and by whom, how and when to eat, and how the foods are acquired, among other things. Therefore, while eating is an everyday action necessary for survival, it requires a multidisciplinary approach for its understanding. This entry explores the relationship between food, eating, and class. Social class refers to the hierarchical organization of individuals in a particular society. It may refer to a caste system based on family social standing, but most commonly, nowadays, class is determined by the amount of wealth and income one possesses.

The topic at hand can be tied to different social dimensions depending on the context it is being addressed. Following the emphasis of this encyclopedia, the entry will focus on developed or resource-rich countries. In such context, the understanding of food and class is increasingly more essential to address health disparities in chronic, diet-related diseases which increasingly affect the poor disproportionately. In addressing this issue, the following entry will begin with an overview of key concepts associated with the study of food and class, followed by an overview of current issues associated with the topic.

The study of food and class can be addressed through disciplines such as nutrition, economics, history, sociology, and anthropology, to name a few. Through these disciplines, various concepts emerge that are important in understanding the issue at hand. This entry will begin by addressing the key concepts of social class, eating, and taste. After the expansion of these key concepts, the entry will discuss the current issues associated and affected by the study of food and class.

Key Concepts in the Study of Food and Class

Social Class

Class is a key determinant of access to services and social goods. At the same time, it is also associated

with education and asset ownership. Two key theorists addressing class were Karl Marx (1818–1883) and Max Weber (1864–1920). Marx addressed the issue of class from the perspective of who owns the means of production in society. In this context, there were two distinct classes: the proletariat, or working class, and the bourgeois, those who own the means of production. For Weber, on the other hand, class was determined by more than asset ownership. Weber addressed social class as the result of the interplay between economic standing, status or prestige (referring to how individuals are esteemed or evaluated in a given social context), and power (referring to that which allows individuals to get their way in society) (Wright 2005).

Nowadays, social class is typically seen in three categories: low, middle, and high. Low social class is associated with greater levels of social deprivation, lower levels of education, and less access to basic commodities. In extreme cases, low-class individuals may lack access to basic necessities, such as housing, health care, and food. Individuals in lower classes are usually in blue collar, unskilled occupations, such as the service industry and high labor occupations. The low-class classification can be composed of those that are employed but earning very low salaries and those who are unemployed, destitute, and without a home to live or shelter. Middle-class individuals are associated with white collar, office occupations, and with higher levels of formal education and income, compared to those in the low social class. The middle class tends to be broad in high income societies and smaller in more developing contexts, with emerging economies. Finally, individuals classified as upper classes have even higher incomes, higher educational degrees, and more prestigious occupations. On concordance with Marx's views, the upper class or elites have control over means of production.

The separation between the lower and the high classes is dictated by the levels of social inequalities in the social context. Societies with big disparities between the low and the high social classes also show broad inequities in diets, health outcomes, educational attainment, and other factors associated with social well-being. Conversely, the gap between the low and the high class is affected

by the level of social mobility in a given context. Social mobility refers to the facility individuals have to change their class status. It is related to equities in access to education, health care, social and cultural capital, and employment opportunities. Social mobility can also be facilitated by the provision of welfare programs, such as income and health safety nets Social Mobility (2013).

While income and wealth are important to class classification, education is often used as another indicator of class, given its close association with social standing. Higher education is correlated with higher income, as people get more economic opportunities from a higher education. Education is, then, key for social mobility and the amelioration of social inequities.

Food and Eating

Simply defined, food refers to a substance that nourishes and sustains life. At the same time, what is considered food, or what is an edible “substance,” varies according to cultural and social contexts. In certain contexts and circumstances, definitions of what is acceptable to eat vary even within a given society. In contexts of extreme poverty or deprivation, individuals may be forced to consume commonly inedible substances, such as dirt, to quench their hunger (MacClancy et al. 2007). These instances are examples of how food, while an everyday concept, is interdependent to the sociocultural contexts in which people live.

Similarly, eating is also a commonplace concept, as an everyday act essential for survival. At the same time, the process of eating is also influenced by different factors. Eating involves several steps, starting with food selection, cooking or food preparation, and culminating with the actual ingestion of food. While these steps are commonplace, each process involved in the act of eating is influenced by a wide array of social, economical, biological, cultural, and environmental factors, including class. Social class dictates what is socially expected from individuals in terms of table manners, for example.

At a more basic level, socioeconomic circumstances affect the types and availability of cooking facilities and the availability of a space for eating

in the home. This is demonstrated by research on the food choice process. Food selection is influenced by class and factors associated with it (Sobal and Bisogni 2009). The research has shown that food choices depend on the time available to procure and prepare food, eat, and clean after the eating episode. Individuals in low social classes, aside from being constricted by the money available to purchase the food, may also be limited by the time they have available to cook or the lack of cooking resources. Time might be an issue across classes, but class influences how time is managed around food. Individuals in higher classes may have better access to technology and hired labor that facilitates cooking under limited time availability. Another important resource is cooking and nutrition knowledge. There, intangible assets are affected by education and family support and attention during the development years, which are also affected by class. Education and nutrition knowledge also influence notions of food quality that influence food selection. This includes brand preferences and access, notions of what is considered healthy or not, and whether people care about the health effect of foods. While all of these factors are important in the food choice process, the main influence in food choices is food preferences, discussed next.

Class, Taste, and Food Preferences

Food taste is influenced by a wide variety of factors, including biological and social influences. However, social class influences the formation of eating habits early in life. These habits and food preferences are built as part of a person’s upbringing and the environment where they live – variables which are affected on income and social standing. This includes the foods and drinks individuals are exposed to as infants and children, which then influence or set a base to their subsequent taste (Drewnowski 1997).

Aside from differences in economic and socioeconomic asset ownership, classes distinguish themselves through different tastes reflected in different consumption patterns, which are influenced by their purchasing power. When discussing class and taste, an important contribution to the topic is the work of Pierre Bourdieu

(1930–2002) in *La Distinction*. In this landmark work, Bourdieu studied taste and preferences across different classes in French society. Among his findings, the taste of the higher classes often dominates the taste of the whole society, defining what is tasteless, tacky, or undesirable. Members of different social classes distinguish one another based on different things they own and acquire. Since members of the high class dictate the preferred taste, those in lower classes will aspire to emulate the taste of those in the high class (Bourdieu 1986).

The differences in classes invariably express themselves in food choices and preferences, as well as eating and dietary patterns. Historically, classes and tastes have been shifting. Before, higher classes were better off when they could acquire higher quantities of food. Then, there were shifts in the qualities of the food consumed. This included an increased taste for foreign, ethnic foods, not readily afforded or accessible by lower classes. These historical shifts in food show how classes distinguish among themselves, with higher classes wanting to distinguish from lower classes, and lower classes wanting to imitate higher classes. Lower classes tend to emulate the taste of those in higher social classes, who at the same time change their consumption patterns to ensure a distinction from the lower social classes.

In the beginning those in higher classes could be distinguished from those in lower classes based on the quantity of foods consumed, with their status allowing them to eat more foods than those in lower classes. As lower classes started to improve their living conditions and were able to access greater quantities of foods and those in higher classes reached a limit on how much they could eat, class distinction then came in the types of foods consumed. Animal source product consumption, as less accessible, became more associated with higher classes. As nutrition patterns continued to evolve, and food becomes industrialized, higher social classes started favoring the new modern industrialized packaged products. For example, with the advent of the microwave, higher classes were able to consume pre-prepared foods, such as “TV dinners,” as a sign that they could afford the new technology (microwaves) and these boxed items.

Higher classes distinguish themselves through the consumption of luxury items. A “luxury food” is defined as a food whose demand is associated to a perception of higher refinement or a qualitative improvement on a basic food. It serves as a tool for class distinction, as its consumption, while highly desired, is not widely attained (Berry 1994). Accordingly, luxury foods are not constant or specific, as they are dependent of specific time and place, where a given food is conceived as extravagant and not a basic necessity or food (van der Veen 2003). Following this, perceptions of luxury change through time. An example of such changes is found in the history of lobster consumption in the United States. Before the nineteenth century, lobsters were in great supply and considered a food for the poor. They were used as land fertilizers and mostly fed to prisoners and servants. Over time, as the supply of lobster diminished, the demand increased and, therefore, its price (Henderson 2005). Nowadays, the lobster is associated with a high price and often considered an example of a luxury food.

The lobster is an example of how changes in supply of a given food affect the social perceptions of the food’s status. Aside from changes in the given food supply, the status of a food can also change with new culinary trends. Two examples of “poor people’s foods” increasingly appearing in high class, expensive restaurants are offal meat and polenta. The consumption of offal meat was associated with poverty, as individuals were consuming animal parts often considered inedible or the animal by-products. In the early modern period, offal meat starts to appear in cookbooks targeted to the elites, broadening their range of culinary taste (Lloyd 2012). Similarly, polenta, as a cornmeal porridge, was traditionally used as a satiating side dish found not only in Italy but in other countries where corn was a diet staple. For example, it is also known as “funche” in the Spanish Caribbean. Nowadays, polenta is served as a side dish in expensive Italian restaurants.

Aside from the changing status of individual foods, social perceptions on cuisines can also change, often, but not always, on par with the cultures associated with such cuisines. For example, in this ever increasingly globalized world,

chefs in higher-end restaurants are experimenting with cuisines from developing or resource-poor countries and offering transformed versions of foods often regarded as street, cheap foods in their restaurants. Examples include traditional street foods, such as tacos, arepas, and various fritters, served as “fancy” appetizers in many new modern restaurants.

The notions of rich and poor people food are cultural dependent. In context as the United States, lower classes are associated with the consumption of highly processed snack food, fast foods, and an unhealthy diet in general. The rich distinguish themselves intended consumption of fresh, organic local foods, or more exotic food preparation, for example, the new gastronomy techniques such as the food foams and other new preparation techniques.

In poor countries, diets tend to be more monotonous, composed of basic staple foods. The ability of being able to afford processed, prepackaged foods is seen as a sign of status, as well as fast foods. Consuming wild, local greens is a sign of poverty. Contrasting this notion, wild, foraged foods are gaining popularity in developed countries, partly tied to the local food movement. In such contexts, higher-class individuals tend to distinguish themselves by selecting more modern foods, such as foreign, imported foods, while those in lower classes tend to adhere more to traditional foods. These foods, at the same time, have different nutritional values, as traditional foods, such as wild, local greens, tend to be healthier than new, modern foods, such as pre-packaged processed foods.

Issues Associated to Food and Class Discussions

Food and Social Interactions

Aside from the need for nourishment, food fulfills and is tied to many human social needs. Food sharing is important in many cultures, and the act of eating is a primary way of interacting with others. In modern society, food sharing might take different forms, from sharing a meal at a restaurant, cooing for friends in the home, to having

“pot luck” gatherings where those invited bring their foods. How individuals interact with one another through food is affected by their social standing. Those in the higher classes may consume more meals outside of the home, at more expensive establishments. The middle class may still enjoy eating out, but may also engage in more home cooking and having family or friends gathering in the homes. In terms of food, those in the low social classes are less able to use food as mean to socialize, as they may not have the resources to take part in different social interactions around food. Poverty, or belonging to lower social classes, carries with it an intrinsic component of deprivation, where those in lower classes cannot take advantage of different social gatherings.

Poverty, Food Deprivation, and Food Preferences

Individuals in low socioeconomic classes have a greater vulnerability to food insecurity and food deprivation. Research has shown that past food deprivation is associated with preference for foods high in energy and fat, given their satiating and “comforting” effect. The importance of food as a source of happiness and comfort is important across all classes, but even more so in situations where the family’s few resources do not allow for fulfilling other nonfoods rewards – for example, while a mother might not be able to afford the latest videogame for her son, when the son ask for a fast-food meal, she will give in, even if she knows other food options are better. Because of the link between food and physiological well-being, the experiences of poverty and food deprivation make the understanding and following of current nutrition advise harder.

Social Class and Diet Quality

There is an inverse relationship between income and the proportion of such income spent in food. Individuals in low classes spend a big percentage of their budget in food, along with other basic necessities (housing, utilities). Given the relatively higher cost of healthy food options, such lack of economic access to food is associated with decreased diet quality. High quality, or nutrient-rich, low energy density diets are associated with

higher socioeconomic status, while low quality, more energy-dense and less varied diets are associated with low socioeconomic status. This is seen in the consumption of foods considered part of a healthy diet, including whole grains, lean meats, fish, fresh fruits and vegetables, and low-fat dairy products (Darmon and Drewnowski 2008).

Food Deserts

The relationship between food and class is mediated by differential access to healthy, fresh foods. Discussions around class and eating touch upon food access inequities and local food deserts found in many low income areas, where supermarkets and fresh food markets are not available, and the poor are dependent on small, “corner” stores selling mostly unhealthy foods along with alcohol and cigarettes. In the United States, for example, research has shown that in low income areas, families spend more time traveling to a grocery store, compared to the national average. While access is expectedly different in urban and rural areas, the issue is most concerning in urban areas with high levels of income inequality and racial segregation. Families in these low income neighborhoods have less access to supermarkets, greatly influencing the types of foods they have access to. This is reflected in purchasing patterns, where lower-class families who are not able to shop at supermarkets buy less fresh fruits and vegetables (Ven Ploeg et al. 2009). This lack of access to healthier, fresh food options partly explains the socioeconomic differences in diet quality, as presented above. Several community interventions are in place to address this issue, including the establishment of farmer’s markets, local food production (urban agriculture), and education programs to promote family resource management for healthier eating patterns (Ven Ploeg et al. 2009).

Obesity Among the Poor and the Fat Prejudice

Disparities in food access and diet quality result in different physical and health outcomes. Obesity used to be a sign of affluence and being taken care of in earlier days, when food was scarce, as seen, for example, in historical women portraits, where

fuller figures were represented. Being thin was a sign of illness and poverty. Nowadays, social prejudices along body shape have changed. There is a social preference for thinness and a negative stereotype concerning fatness. These stereotypes include negative perceptions of overweight individuals as “not having will power,” among other negative adjectives (Crandall and Schiffhauer 1998). At the same time, fatness is associated with lower socioeconomic classes. Lower income and social standing, as mentioned above, are associated with less access to healthy food options. At the same time, low income areas present fewer opportunities for daily physical activity in so-called “obesogenic” environments, where the lack of healthy food choices combined with perceived lack of neighborhood safety, lack of outdoor space (playgrounds, parks), and poor infrastructure and transportation options increases the individuals’ vulnerabilities to becoming overweight or obese. A second issue at play is the psychological consequences of poverty, which increase stress levels and, at the same time, vulnerability for excessive weight gains and other health conditions, such as hypertension and heart disease. Conversely, obesity is also linked to social class, by influencing social opportunities through existing social prejudices (stigmatization and discrimination), limiting an individual’s ability to improve his/her socioeconomic situation (Sobal 1991).

Summary

The topic of food and class is an important one across many disciplines. Food is much more than nourishment – it serves as a way to mark status in society, a vehicle for socialization, and a way to increase mental well-being, among other things. While food fulfills many different social and psychological needs, it is also closely linked to overall health. As social classes distinguish themselves through different tastes and food preferences, these differences are associated with health disparities and other issues, such as disparities in housing and neighborhood location and social stigma related to obesity, as a consequence of poverty and different eating patterns.

Introduction

Assumptions regarding the relationship between the ontological categories of “food” and “drug” undergird a substantial amount of academic discourse and also function as key components in worldviews beyond the academy. Despite the prevalence of these ontological assumptions, little work has been done in foregrounding them to allow for critique and consideration of alternative perspectives. This entry provides an overview of this emerging discussion within food ontology, as well as various perspectives on the food-drug relationship and ethical implications of these views. The term “drug” is employed to refer to a

broader category of substances which encompasses “medicine” while also including substances used for recreational, religious, and other nonmedical purposes (e.g., drugs in the detrimental/addictive sense).

Food and Drug Ontology in the Philosophy of Food

While philosophers have paid an increasing amount of attention to the topic of food in the last 20 years, they have focused almost solely on ethical issues surrounding food without attending to related ontological (and other philosophical) questions. In the introduction to his edited volume *The Philosophy of Food*, David M. Kaplan illustrates the importance of examining food within other philosophical domains, such as metaphysics (which includes the subfield of ontology, the study of being):

We presuppose some conception—however vague—of what food is whenever we eat or identify something as food. Different conceptions can have real consequences for our health, the environment, and the economy. Metaphysics makes these implicit assumptions explicit by examining the very notion of what food is and what property or properties make something food. The answers to questions concerning the nature of food are not at all obvious. Nor are the answers to other metaphysical questions about the difference between natural and artificial food, the identity of food over time (from raw to cooked to spoiled), the difference between food and an animal, or the difference between food and other edible things (such as water, minerals, or drugs). (Kaplan 2012)

Encounters with food and the act of identifying a particular edible thing as a member of the category “food” entail some presupposition about what food *is* and about the criteria required for some edible thing to adequately count as food. The different presuppositions that people have about the nature of food, or about what is *not* food, affect their experiences of specific substances. Decisions on whether to treat edible things as foods, even when these decisions are made implicit, entail repercussions which have impacts. Thus, ontological and ethical perspectives are importantly linked, as views on how

something should be treated rest in part on assumptions and presuppositions regarding what people take those things to *be*.

While food ontology is a fledgling area of study in itself, a handful of scholars have begun to explicitly examine the food-drug relationship in particular. Some philosophers have reflected on the category of “functional foods” as one area in which the perceived boundary between food and drug is called into question. Kaplan characterizes functional foods as “those that have added ingredients believed to provide additional health benefits,” tracing the practice of creating functional foods to the beginning of the twentieth century and the development of iodized salt, the fortification of milk and cereal with vitamins and minerals, and the addition of fluoride to water (2007). He notes that more recent instances of functional foods, such as margarine that is purported to lower cholesterol, have been designed with the intention of replacing medicine with food. At the same time, the United States lacks a legal definition for functional foods, which also results in a lack of regulatory oversight in the production and marketing of these products. This inadequate regulation, in tandem with the growing popularity of functional foods and people’s use of them in place of prescription and over-the-counter drugs, is disconcerting. Kaplan argues that “[a]s the line between food and drugs becomes increasingly blurry, the FDA should require that functional food labels carry the same disclaimer [...] as dietary supplements” (2007).

Gyorgy Scrinis also grapples in innovative ways with the ontology of food and the distinction often made between food and drug. Scrinis coins the term “nutritionism” and expounds on what he refers to as nutritional ideology, the reductive approach to viewing and understanding food that undergirds contemporary nutritional science (2012). Nutritionism entails a reductive view of food on which foods are understood primarily in terms of the nutrients and other component parts that constitute them. Proponents of nutritionism often see the value or disvalue of foods as stemming from the presence or absence of particular components. This ideology is employed in the marketing claims used to promote the sale of

various foods. For instance, the engineering and marketing of “low-fat” foods entail a view of fat as inherently bad and the absence of fat as inherently good. This reductive approach ignores nuances such as the existence of fats that are beneficial when consumed in moderation, as well as the way that fats can interact with other food components to enhance nutrient absorption. Nutritionist ideology also undergirds much of the popularity of dietary supplements, where a particular vitamin or nutrient is seen as having value apart from the food source from which it is derived.

This ontological view is directly tied to the development and proliferation of functional foods. Scrinis observes that there are many historical precedents for the possibility of viewing food as medicine. However, he is also quick to distinguish the view of functional foods as medicine from traditional approaches which call into question the boundary between these categories:

[T]he more traditional or premodern approaches to food as medicine involved recognizing the medicinal properties of whole foods and utilizing them in their received, whole, or unprocessed form. The modern era has been characterized by a fragmentation of food and medicine at the biochemical level and the development of distinct industries producing processed industrial foods, on the one hand, and chemically synthesized medicines and pharmaceuticals on the other. In the contemporary era, the emergence of the functional foods concept does not herald a simple return to traditional approaches to food as medicine. Rather, functional foods can be understood as a postmodern food category that represents the reintegration of industrial foods and chemical medicines *at the biochemical level*, to the extent that this involves inserting nutrients, food components, and other chemical compounds into processed reconstituted foods. (Scrinis 2012)

Through the lens of nutritionism, functional foods can be seen as blurring the boundaries between food and drug while also maintaining that these categories are distinct in the absence of human intervention. That is, food is not inherently medicinal and cannot become medicine until humans infuse it themselves with drug-like properties. This is markedly different from perspectives that view food and drug as ontological categories that are intermingled with one another

in the absence of human intervention at the chemical level. One example of such a view can be seen within Ayurvedic medicine, a traditional form of medical theory and practice from India which has recognized the preventative and convalescent roles of food for hundreds of years (Sesikera 2014). As an Ayurvedic practitioner and a professor, Sanjeev Rastogi writes, “[w]e still have a long way to go before we truly understand how to remain healthy with the help of the strongest medicine ever evolved – food” (2014).

Perspectives Outside of Philosophy

Taking the food-drug relationship as an object of inquiry is not strictly the purview of philosophers, and many academicians and interested parties beyond the academy have turned their gaze toward this and related topics long before the emerging popularity of areas of specialization such as the philosophy of food. Thus, this entry also engages with literature from anthropology, psychology, and popular culture. At the same time, many philosophical presuppositions and implications remain largely implicit within these works. In the following sections, this entry provides a brief review of relevant categories of extra-philosophical literature with the aim of foregrounding their philosophical positions.

Anthropology of Food and Medicine

Since its emergence as an academic field in the nineteenth century, anthropologists have featured food prominently in their studies, taking it seriously as a key topic of inquiry (Mintz and Du Bois 2002). Given the attention that structures of food production, distribution, and consumption have garnered within anthropology, a number of anthropologists have also performed research that bears more directly on the food-drug relationship. One of many examples of this can be seen in the edited volume *Eating and Healing: Traditional Food as Medicine*. In the book’s introduction, the editors reflect on the status quo of the study of food and medicine while also expressing their

own principled position on the relationship between these categories:

[W]hat we both learned in our respective formal educations in pharmacy and anthropology was that food and medicine were two different arenas. Only recently are we learning the importance of the food-medicine linkages. Plants may be used both as medicine and food, and it is difficult to draw a line between these two areas: food may be medicine, and vice versa. (Pieroni and Price 2006)

As articulated here by Pieroni and Price, the mainstream contemporary view of the food-drug relationship (embodied in both pharmacy and anthropology) entails that these are distinct ontological categories. Even in cases where there is overlap (e.g., the manufacturing of functional foods discussed above), this is still seen as a result of the intentional combination of food and medicinal components through the use of technology. Contra this position, Pieroni and Price defend what could be described as a “continuum-based” position, where food and drug are interpreted as existing on a continuum rather than being in a dichotomous or binary relationship with one another. The authors of the book’s 16 chapters go on to illustrate the editors’ thesis through numerous empirical examples of the medicinal use of plants within cultures from around the world, including groups in Tibet, Thailand, Albania, Spain, Morocco, Kenya, Patagonia, and many others.

This position is also taken up by anthropologist Nina L. Etkin and can be observed throughout much of her work, including her book *Edible Medicines: An Ethnopharmacology of Food* (2006). Etkin writes that, while there have been studies within the hard sciences on the ways that foods impact health, insufficient attention has been paid to the “nonnutritive” qualities of food. This discrepancy, she continues, can be observed in “conventional studies that inventory medicines or foods but do not consider that an item may not be simply one or the other” (Etkin 2006). Again, Etkin raises this question of the food-drug relationship by reference to cross-cultural uses of foods. One example from Etkin’s research is the Hausa people of Northern Nigeria’s use of plants as food as well as in the treatment of

gastrointestinal disorders (Etkin and Ross 1982). Plants such as the Egyptian mimosa, baobab tree, onion, garlic, cashew, and capsicum pepper are used to treat ailments including dysentery, dyspepsia, nausea and intestinal worm infection. Rather than only examining these and other plants as food sources, Etkin and Ross suggest that “an examination of these plants within a therapeutic context facilitates a more comprehensive understanding of the role that these plants play in the diet” (1982).

The anthropological work that is closest to an explicit philosophical treatment of the food-drug relationship is Nancy N. Chen’s book *Food, Medicine, and the Quest for Good Health: Nutrition, Medicine, and Culture* (2009). In her preface, Chen clearly sets out the theoretical approach that she develops and defends within her book:

In this book I examine the intersections between food and medicine, a relationship that has all too often been obscured because the two are frequently seen as entire different categories. Thinking about food and medicine as part of a continuum rather than as two separate arenas offers important insights into the consumption of food and the healing process. [...] Keeping food and medicine separate has consequences, just as dissolving these boundaries would. Rather than disentangling food and medicine from each other, I try to consider how cultural frameworks may or may not enable a keen understanding of eating and healing as part of a continuum. (Chen 2009)

Chen goes on to review the historical use of foods for medicinal purposes within traditional Greek, Islamic, Chinese, and Indian medical systems in support of her claim that these cultures interpreted food and medicine as categories that could not be separated from one another. Chen’s narrative traces the shift toward viewing food and medicine as separate categories through the rise of synthetic medicine and the power of the pharmaceutical industry, as well as the way that these categories have intertwined once again, as Scrinis also describes, through the creation of functional foods. Ultimately, Chen argues in favor of viewing food and medicine as categories with blurred boundaries, taking a continuum-based, rather than a dichotomous view of the food-drug relationship. This view, according to Chen, allows the

consumption of food to be seen as a legitimate avenue toward healing and medicating, rather than promoting a reliance on the ingestion of prescription or other synthesized drugs alone.

Psychological Perspectives on Food and Drugs

As mentioned in the introduction, this entry is not limited to an examination of drugs in the medicinal sense, but also encompasses an examination of drugs in the detrimental/addictive sense. It is this latter sense of the term “drug” that necessitates discussion of relevant psychological literature, as there has been recent study and debate regarding the potential for foods to be addictive and harmful in ways that may (or may not) merit calling into question whether (at least some) foods could be accurately viewed as drugs or as having drug-like properties. The edited volume *Food as a Drug* collects some illuminating perspectives from leading psychologists on this debate, particularly regarding the viability of the use of an “addictions model” for treating food-related health problems such as obesity. In the preface to this volume, the editors provocatively raise the question:

Why should anyone consider food to be a drug? Food is necessary to human survival and yet some individuals seem to have significant difficulties controlling their intake. [...] Obesity and eating disorders extract tremendous societal and personal costs in the forms of increased risk for disease and death, health care costs associated with long-term treatment and, given their multi-factorial nature, many experts recognize them as chronic diseases that require long-term, multidisciplinary management. (Poston and Haddock 2000)

While the editors proceed to remark on the rise of the “food as drug” view within popular culture, the chapters therein tend to support a position which is ultimately critical of this approach. For example, C. Keith Haddock and Patricia Dill argue for the rejection of the addictions model of obesity. According to the authors, this model rests on the claim that “[t]he dependence and lack of control over these food substances is undergirded by [...] the psychoactive properties of foods” (Haddock and Dill 2000). After surveying a

number of studies on the subject, the authors conclude that, while certain foods may have some effects on dimensions of human experience such as mood and behavior, these effects are not sufficiently similar to the psychoactive properties of drugs to warrant the application of an addictions model to treatment of food-related disorders. In addition, Haddock and Dill write that “[c]onvincing patients that certain foods are highly addictive and that they are powerless to control their compulsive eating may promote feelings of deprivation and low self-efficacy” (2000). This branch of scholarly literature on the subject enforces a paradigm of relegating food and drugs to separate domains, ontologically as well as in practice.

Countering those who are opposed to seeing and treating foods as drugs, there are also a growing number of psychologists who are open to the possibility that these categories are more deeply intertwined than others have granted. In their volume *Food and Addiction: A Comprehensive Handbook*, psychologist Kelly D. Brownell and psychiatrist Mark S. Gold assemble a variety of scientific perspectives that take a more nuanced approach to this question, addressing related topics including the neurobiology and psychology of addiction, regulation of eating and body weight, clinical and public health approaches, and policy implications. After reviewing and reflecting on the myriad studies included in the book, Brownell and Gold state very clearly in their concluding remarks:

Food can act on the brain as an addictive substance. Certain constituents of food, sugar in particular, may hijack the brain and override will, judgment, and personal responsibility, and in so doing create a public health menace. [...] Just like drugs of abuse, brain-rewarding effects or reinforcement from food can lead to loss of control. [...] The addictive impact of food may be a contributor to the global health crises created from obesity and diabetes, to the point where legislative and legal efforts might be informed by advances in this field, much as they were with tobacco. (Brownell and Gold 2012)

This perspective contrasts with the aforementioned views of Haddock and Dill, where they clearly lament the possibility of imparting a sense of compromised autonomy and willpower

to patients dealing with obesity and other eating disorders. While Brownell and Gold do not defend an absolutist position such that they consider all food to always be addictive, they present an array of evidence in support of the potential for at least some foods (e.g., sugar) to be addictive for some people.

In the same handbook, Daniel M. Blumenthal and Gold argue that “food and drugs of abuse exist along a spectrum of substances that compete for access to the same dopamine-mediated reinforcement sites in the brain,” such that indulging in one type of substance can decrease craving for other types (2012). It is for this reason, the authors point out, that rehabilitation clinics as well as addicts themselves have used high-sugar foods to curb desires to ingest drugs (Blumenthal and Gold 2012). Countering the aforementioned opposition to an addictions model for obesity treatment and implicitly calling into question the ontological status and appropriate interpretation of the relationship between the categories of food and drug, psychologist Elliot M. Blass argues succinctly that “[o]ur task as health professionals is made more manageable by recognizing extreme obesity as a form of drug addiction, a maladaptive behavioral/physiological/cognitive constellation that is notoriously difficult to break” (2012).

Beyond the interpretation of food as drug for clinical purposes, Blass and others have argued that there are clear policy implications that such a recognition entails. In an article in *Nature* entitled “The toxic truth about sugar,” the authors argue that, similar to substances like tobacco and alcohol, sugar can be toxic and has clear potential for abuse and for negative societal effects (Lustig et al. 2012). Hence, there should be government-imposed regulations and public health directives regarding the sale and consumption of sugar. The authors make some preliminary recommendations, including adding taxes to processed foods that contain added sugars, strengthening licensing requirements on vending machines and snack bars where such products are sold, and zoning ordinances for fast-food restaurants and convenience stores around schools and low-income communities (Lustig et al. 2012).

Food and Drug Ontology in Popular Culture

As with many controversial issues, concerns about the addictive and harmful potential of edible things range from emphasizing caution and moderation to advocating more extreme positions. A sensationalist bent regarding public perceptions of sugar, for example, can be detected in some popular, nonacademic writing on the subject. On the opening page of his book *Natural Health, Sugar and the Criminal Mind*, J.I. Rodale writes, “Napoleon, Ivan the Terrible, and Hitler, juvenile delinquents and hippies may have something in common – were they sugar drunkards?” (1968). Rodale moves beyond concern for the addictive potential of sugar to ruminate on and present evidence in support of what he takes to be a correlation between sugar consumption and criminal behavior, utilizing examples including Lee Harvey Oswald and the above historical figures and social groups to make his case. Less extreme perspectives on food as a drug in the detrimental/addictive sense have also taken hold in popular culture, as illustrated in *Redbook* magazine editor Sunny Sea Gold's book *The Good Girl's Drug: How to Stop Using Food to Control Your Feelings* (2011). Gold draws on her personal experiences suffering from and fighting binge eating disorder, consulting mental health, nutrition, and fitness literature to provide understanding, support, and preventative/healing strategies for others dealing with eating disorders.

Finally, the potential for seeing food as medicine has also spread beyond academia in palpable ways. One example of this is described in the *Yes! Magazine* article “Is Cooking the Future of Medicine?,” which describes recent efforts at Tulane University's Goldring Center for Culinary Medicine in New Orleans (Grewal 2016). While many medical students have minimal nutritional education, members of the Goldring Center are teaching medical students to cook in order to help them gain insight into nutrition and health and to impart this knowledge to their own patients. Classes at the center are open to the public, and medical students are “trained to prescribe healthy eating to their patients” (Grewal 2016). Twenty medical

schools have adopted similar programs based on Tulane's model, and there is hope that the emphasis on nutritional education in medical school will help to shape the future of modern medicine in positive ways, leading to developments such as the greater emphasis on preventative care and the reduction of common health problems through food selection and home preparation.

Conclusion

In conclusion, this entry provides an overview of the development of food ontology within the philosophy of food, as well as various perspectives on the food-drug relationship within philosophy, anthropology, psychology, and popular culture. These varying interpretations of food and drug include both "continuum-based" approaches, where food and drug are seen as part of a continuum of edible substances, as well as "dichotomous" approaches, where food and drug are seen as distinct ontological categories. Each set of positions has its own proponents, advantages, disadvantages, and ethical implications. Finally, within the fledgling areas of food and drug ontology, it is important for these perspectives to be subject to philosophical scrutiny in order to foreground their often implicit assumptions and implications for critical examination.

Introduction to Food and Health Policy

What is food policy? Miller and Deutsch (2009) discuss what constitutes food studies; they say that food studies are not really the study of food itself but the study of the relationship between food, the human experience, and food (Brillat-Savarin 1976; also see Brillat-Savarin and Food). Miller and Deutsch (2009) outline areas of study such as food science, agricultural science, culinary arts, public health nutrition, and agro-economics, to name but a few areas which they see as incorporating food studies. Food policy incorporates all of the areas but is more than even the study of the relationship between food and the human experience. Food policy is more than health and more than just agricultural policies or even nutrition policy as individual strands; it is the interconnectedness and

sometimes even the disconnect between these various areas.

Food policy, as an academic subject, is the study of the relationship between all these areas of study and how policies are formed or not developed despite the weight of the evidence (Lang et al. 2009). For a long time, transport policies were not considered as having much to do with food policy; however, now they are seen as integral in terms of how food is transported from where it is grown to where it is consumed. Food policy can also be defined by the absence of a written policy or even benign neglect of an area. The failure to relate food production to oil and oil prices was for a long time a major commission in food policy; the food system relies on oil, oil to produce fertilizers for food, oil to power the machines to harvest it, oil to process it, and oil to distribute it. There is an argument that food policy should not become a distinct area of endeavor seeking instead to become part of and embedded in other policies. Like the concept of health in all policies, food should be in all policies. This in reality is difficult to achieve, and the fallback position is to develop a separate food policy. This usually takes the form of a nutrition-based policy (Milo and Hesling 1998; Caraher and Coveney 2004).

It becomes clear that healthy food-related policies can have an impact on other issues such as environment, considering the example of campaigns to increase fruit consumption in the global north. Fruit consumption has increased significantly since the mid-1970s; this has been largely accounted for by the very sharp rise in purchases of fruit juice which does not provide equivalent nutrition to its fresh counterpart. This fruit juice consumption, however, is often of juices from long-distant fruit, notably oranges from Brazil. A study by the Wuppertal Institute in Germany calculated that 80% of Brazilian orange production is consumed in Europe. Annual German consumption occupied 370,000 acres of Brazilian productive land, three times the land devoted to fruit production in Germany. If this level of German orange juice consumption was replicated worldwide, 32 million acres would be needed just for orange production. The increasing expectation that fruit

juices should be available throughout the year also contributes to this rise in consumption. If countries in the global north substituted orange juice for what they can grow and produce regionally, then this would contribute to a reduction in the environmental impacts. Of course what is occurring is a social phenomena in that orange juice is seen as something more luxurious and is imbued with concepts of sun and health. So health policy can have impacts on trade and environment, but equally areas not immediately related to food can have an impact on food and nutrition; this can be trade policies or even transport policy (Kranendonk and Bringeau 1994). This helps make the case for food policy which is wider than just nutrition or even production but which incorporates elements of trade and global equity (see also “Free Trade and Protectionism in Food and Agriculture”; “Environmental Ethics”; “Environmental Justice and Food”).

Most of the existing food policies that exist are divided into two groups; the first are those that have nutritional health as their focus and the second group are agricultural/processing policies (Bronner 1997; Milo and Hesling 1998). The dangers inherent in both approaches are that there is no sense of joined-up policy. This is despite calls for the development of joint food and nutrition policies by the World Health Organization, following the 1992 International Conference on Nutrition. Egger and Swinburn (2010) make the link between the nutrition implications and the planetary ones in the subtitle of their book *How We're Eating Ourselves and the Planet to Death*. There is of course a danger in assuming that nutrition equals food policy and occupies the moral high ground. Lang et al. (2009) set out a typology of “three nutritions.”

- **Life Science Nutrition:** food cannot be seen only as a totality of its micro and macro components that influence health, the biomedical approach (see also “You are What You Eat”; “Eating, Feeding and the Human Life Cycle”).
- **Social Nutrition:** food can also be seen as a mean of socialization, linked to cultures and other social contexts.

- **Eco-Nutrition:** food is now seen as an integral environmental component that affects and is being affected by the environment and hence needs to be produced and distributed in an ecological way. This is an attempt to relate nutrition to sustainable growing and processing.

These concepts are broadened below in the section on ways of conceiving food policy. In the sections that follow, the following are set out food and public health policy with the tensions between health and production policies set out, the new malnutrition and the shift from hunger to hunger and obesity in the nutrition transition, and issues about taxation and subvention in food and health policy including taxation as a means of changing behavior. These are dealt with under the four headings of globalization power and control in the food chains, ways of conceiving healthy food policy, food inequality and the nutrition transition, and finally interventions in public health and obesity prevention from tax to subsidy.

Globalization Power and Control in the Food Chains

Figure 1 highlights the concentration of power for the majority of foods grown and processed in Europe. The power and control are located at

Food and Health Policy, Fig. 1 Food and Health Policy

the bottleneck with the 110 buying desks who determine the type and price of goods that eventually appear on the supermarket shelves. This has implications for growers and the consumer with what is called the funnel effect, with this process of concentrating power being repeated globally with respect to most commodities. It results in a concentration of buying power, with fewer buying desks and fewer outlets and less power in the hands of the grower (Monteiro and Cannon 2012). The buying desks of the large transnational corporations (TNCs), whether retail or fast food, do not want to be dealing with a large number of small producers. This leads to concentrations in the growing and production of food. There have been changes over time in who controlled the food system in the early 1900s farming was dominant with the manufacturing sector assuming dominance in the middle of the century; this changed in the 1960/1970s to manufacturers and wholesalers with retailers emerging as dominant in the last 20 years of the twentieth century and in this century. This dominance by the retailers is being challenged by the food service sector (fast food, takeaway, and restaurants). Globally power is concentrated in a small number of TNCs; it is estimated that 20 major companies control up to 80% of global food trade (Lang et al. 2009). Key impacts of globalization of the food system include:

The supply chain funnel in Europe from farmers/producers to consumer

- Development of large multinational companies who control what is grown, where it is grown, and prices
- Loss of biodiversity
- Homogenization of culture
- Less emphasis on public health

(See also “Community-Supported Agriculture”; “Food Deserts”; “Food Security”; “Trade and Development in the Food and Agricultural Sectors.”)

Public health concerns are subservient to those of business and trade. As was seen above, with orange juice, there are also problems when nutrition policy ignores or neglects

to account for wider impacts such as those on the environment.

The concentration of power can be further represented by a north/south divide with the major international companies being based or originating in the rich north. The funnel or wine glass model represented in Fig. 1 is replicated across the globe within and between countries in terms of food power, trade, and control of the food chain. A small number of transnational corporations have power at the stem of the wine glass, controlling those who produce food and controlling the choices of those who consume (the industry calls this choice editing). This has implications for growers and the consumer with what is called the funnel effect, with this process of concentrating power being repeated globally with respect to most commodities. It results in a concentration of buying power, with fewer buying desks and fewer outlets. All this leads to concentrations in the growing and production of food.

An example of the global power of the food industry and the economic impact on nation states comes coffee growing. Globally, five major roasters are Procter and Gamble, Nestlé, Sara Lee, and Philip Morris with 40% of world trade. The key driver is price for the major roasters. So they go where the coffee is cheapest; in recent years this has been the Far East (Vietnam) where World Bank policies have resulted in a glut of coffee resulting in lower prices for growers globally. So the basic grade coffee bean, for instant coffee (which accounts for about 80% of the total coffee market), can travel across the globe for processing. In 1990 the world coffee trade was worth US \$30billion, of which producing countries received US \$12billion by 2004 global revenues were in the order of US \$55billion but only US \$7billion went or stayed in exporting nations. The cost for consumers stays the same or increases slightly; the main beneficiaries are the roasters and retailers.

So the point is that the old-fashioned notion of food policy as being simply related to health no longer holds true, if indeed it ever did. The danger is that food and health policy

can be seen as merely a way to pick up the pieces after the event. So ill-health is the consequence of unbridled and unregulated food chains (Egger and Swinburn 2010). If food policy is to be successful, it needs to engage with the food chain in its entirety. This leads to the idea of conceptualizing the food chain and food policy's relationship to it.

Ways of Conceiving Healthy Food Policy

Lang and Heasman (2004) set out three paradigms of the food system (see Fig. 2 below which is based on these paradigms). These are:

The models of the productionist paradigm of food production (*top*) and the ecological paradigm (*bottom*) (Lang and Heasman 2004)

1. A productionist approach
2. The life sciences approach to health
3. An ecologically integrated approach to health and environment

These are similar to the three “nutritions” mentioned earlier (Lang et al. 2009). The middle one is highly technical and based on technology and modern advances in nutritional knowledge. It offers hope for improvements in health and nutrition through technology and modern advances in nutritional knowledge (Gibney 2012). This will be delivered through novel foods, new technology, and changes in health-care screening. There remain two problems with such an approach: the first is concerned with the availability of such initiatives introducing a growing inequality between the countries of the north and the south; the second is the danger of it widening inequalities within countries. It remains questionable if such an approach can be seen as a population approach. There are two approaches in public health nutrition, the universalist and the selectivist. The former targets the whole population on the basis that small changes across the whole population are preferable to big ones in a small subsection of the population.

The productionist paradigm sees human health best served by an efficient and productive food chain built on a model of more and greater efficiency. The second agricultural revolution following WWII in the shape of better and more efficient production, delivery, and retail is now being promoted through the development of genetically modified foods and other advances in technology. The drive is profit and the growth of corporations. The proponents of this model also claim it will address food security, although this is only in terms of the production of the total amount of food produced, and these claims do not address issues of access or rights to that food (Sen 1981, 1997).

The ecological paradigm works from a different set of values where the drivers are human and environmental health, and the system works to deliver on these values. Much as it would be nice to believe that this is the desired outcome for all players in the food system, there are many tensions inherent in this models and many vested interests at play; the neoliberal economic model of free trade and the removal of barrier including public health ones to trade are paramount (see examples of this in “Fair Trade in Food and Agricultural Products”; “Public Institutional Foodservice”).

As noted above, the majority of food policies are developed from a health perspective; this is as much about historical antecedents as about the logic of the process (Ostry 2006; Caraher and Coveney 2004). Over time, health policy makers became aware that the development of health policy could not happen in the absence of working with agricultural, business, and economic interests. As the food chain became more global and power became concentrated in a number of global companies, nation states became less involved in policy making, leaving this to the private sector and global governance institutions such as the World Bank, the World Trade Organization (WTO), and regional trade bodies such the European Community/Union and North American Free Trade Agreement (NAFTA). The politics of food became more complex, and the influences shifted (Schanbacher 2010).

F

Food and Health Policy, Fig. 2 Food and Health Policy

The 2009 report “A Future for Food” from the Public Health Association of Australia raises many of these issues and calls for a “national integrated food policy” for Australia, which

would involve all the food sectors including the food industry. The report highlights a number of dilemmas for Australia which include questions about:

- The appropriateness of setting limits to the amount of food to be eaten and foods to avoid which are less sustainable, e.g., meat consumption
- The balance between land to grow feed for animals and land to feed humans directly
- The role Australia should play in addressing concerns re world food security, i.e., plans for Australia to produce sufficient food to feed the emerging economies of Southeast Asia

These are all challenges both to the current food system and the food choices individuals make every day. Irz et al. (2003) have estimated that to bring food production into line with WHO/FAO healthy eating guidelines (i.e., an integrated food policy), production of the following would need to be decreased:

- Pig meat by 5%.
- Butter by 13%.
- Cream by 18%.
- Animal fat by 31%.
- Soybean oil by 14%.
- Rapeseed oil by 30–35%.

And production of the following would need to be increased:

- Fruit production UP by 100%
- Vegetables UP by 100%
- Cereals production UP
- Nut production UP
- Fish catch and production UP (Irz et al. 2003)

Despite the calls for joined-up policy and even for the development of national food and nutrition policies, this has not resulted in many such joined-up policies. The reality is that agricultural, trade, and financial interests gain the upper hand. Another way of addressing the problem is to ensure that all policies are food “proofed.” So a set of criteria are developed against which all policies are measured against. Key among these criteria should be the issue of preventing further inequalities and pulling back existing ones – the topic which is addressed next.

Food Inequality and the Nutrition Transition

At a global level, inequalities are stark with the rich-developed nations enjoying choice and food safety at a time when the Millennium Goal to reduce hunger is not being met. In fact, the numbers at risk have increased (George 2010). These divides are sometimes stark and obvious as a section of the population engages in conspicuous food practices and consumption, while others suffer “want.” While these global divides are often apparent and somewhat visible, food insecurity within developing and developed economies is seen as something of a myth and often viewed as being self-inflicted and due to inadequate food knowledge and skills on behalf of the individuals or families concerned. In the light of the recent global economic crises, countries in the global north are seeing an increase in poverty and a consequent rise in food poverty. This is evidenced by the number seeking food aid from charitable and state institutions (Poppendieck 1999, 2010).

As the background to the changing nature of food poverty and insecurity, the world is experiencing a “nutrition transition” (Caballero and Popkin 2002) with diseases, such as obesity and type II or late-onset diabetes, previously associated with affluence, middle age, and lifestyle factors, now skipping a generation and occurring among younger members of society and in low-income and marginalized groups. This has in the past been preceded by changes in the makeup of population demographics and generally better health status due to infectious diseases being controlled and improvements in nutrition, housing, maternal health, and health care. The “nutrition transition” model helps explain some of these effects with overabundance and want existing in the same societies. The nutrition transition is also occurring in the developing world with diseases of undernutrition existing side by side with non-communicable diet-related diseases. While hunger is still evident in developed economies, 47 million Americans will go hungry today. This is counterposed with the obesity epidemic. The paradox is that the want and abundance in terms of overconsumption exist in the same cohorts (Pena

and Bacallao 2000). So this group goes hungry at times and overconsumes at others – often with the intake of inappropriate foods. This paradox can be seen in the work of Popkin, and his work is worth reading to untangle these complexities. There is always the danger that in seeking explanations and solutions, the focus is on individual behavior.

The choices that people are making in the name of what might be called the new concerns with ecological health mirror the facts of life of those who live with “want” – that is, restricted choice and diets. The distinction is, of course, that of choice – if I chose to eat less meat and consume less or eat a locally based diet, then that is different than if this consumption is a matter of necessity and lack of choice (see Kingsolver 2007; Pollan 2009 for examples of this new austerity as lifestyle choice). At the same time as these changes in food security/poverty, we are also witnessing a growth in new ways of dealing with food and which has been labeled the “new austerity” movement (Caraher 2011).

A short example may help illustrate some of the above contentions. With the demise of the Soviet Union, the Russian population experienced shortages of foodstuffs. Rooftop gardening emerged as one way of addressing urban food shortages and adding to the diet. In one district in St. Petersburg, 2000+ tons of vegetables are grown. This arose out of the need to meet food shortages and food insecurity (World Health Organization 1999). On a similar climatic level in Michigan but a few degrees south in latitude, there is a group of food consumer “activists” – those committed to “eating locally” in Michigan. The group have adopted the name *Edible WOW* (WOW takes its name from three densely populated counties in southeast Michigan: Washtenaw, Oakland, and Wayne). These are part of Edible Communities’ network of local food publications (see www.ediblecommunities.com). The reasons for the actions in Michigan are very different from those in St Petersburg; the WOW group is focused on eating locally, methods of production, and the origins of food, all admirable aims. But here, are two groups doing similar things but for different reasons, one because they had to, the other because they chose to. Developments such as

WOW have also been critiqued for being “middle class” and niche in their operations. They can be critiqued for the level of social skills and social capitals needed to adopt an alternative lifestyle. The irony is that some of the rich chose to live in ways that the poor or peasant societies lived; they can do this as they have the resource and capabilities. The poor, now, have less choice and power to do this as their foodscapes are controlled by TNCs and the power of availability and advertising. Contemporary calls in the United States to address “food deserts” focus on deprived areas having a supermarket or large grocery store which sells a range of fruit and vegetables (United States Department of Agriculture 2009). This is a reflection of the dominant market system. Michelle Obama, the US first lady, announced a US \$400 million effort to eradicate food deserts within seven years; this entailed working with key retailers to ensure all communities have a supermarket to shop from; key partners include Wal-Mart. All this at a time when the alternative movement is growing, but for the poor and disenfranchised, there it appears no “alternative” but the mainstream. So it may be that future development of alternative food systems and networks contributes to a further sense of alienation and creates a further gap in the social divide (see examples of this in Public Institutional Foodservice; Slow Food).

At a time when well-off consumers are moving away from the dominant system, the dominant system is being brought closer to the poor. This development of a modern day “Walden” (Thoreau 1854/ 2004) or return to an ideal of bucolic living, which is more easily accessible and available to those with capital assets and resources. So some, with self denial and lifestyle choice as part of the “new austerity” such as 100 mile or 100 km diets or locavore-based diets, are expressing a form of social capital which has its roots in the protestant ethic of denial and the greater good (Belasco. 2007; Poole 2012). As Gopnik (2012, 93) asks “*who is likelier to eat the today the diet of the American farmer or the Russian peasant of the Old Country-brown bread and freshly grown local vegetables, free-range chicken and raw milk cheese- the farmers’ great-grandchildren,*

or the professor of comparative literature at the nearby liberal arts college?” But, ironically, this may not be an option for those on low incomes or disenfranchised in other ways (see as an example of this new genre Kingsolver 2007).

At the same time as the nutrition transition, the face of food poverty is changing with undernutrition and micronutrient deficiencies now exiting alongside the problems of overnutrition. This is important to note as the changing nature of food supply and consumption is leading to a need to revisit and reconceptualize our ideas of food poverty; see Table 1 for how the new or modern food (in)security can be conceived. Food inequality needs to be key to any food policy development; in fact, it can be argued that the key function of any food policy or food in other policies should measure the impact of any increase in food inequality or access. The key point is not that all forms of alternative food create inequality but that some do and should be monitored to ensure they do not increase inequalities of access and provision to food. Eating seasonally was once the preserve of the poor now with the development of what Gopnik (2012) calls the modern “moral taste”; seasonality and eating locally are fast becoming the terrain of those with resources. The price of food poverty or insecurity in the past was seasonal eating; now the rich pay money to eat seasonal and local food.

The “old” and “new” forms of food poverty and (in)security.

The changes in any society are complex and subject to local food culture and customs. However, they tend to follow a pattern whereby in the first stages of development, the rich adopt the food habits of the rich first-world countries. This can take the form of consumption of takeaway and processed foods, all of which can contribute to chronic diseases such as heart disease and cancers (Popkin 1998). The reasons for this are twofold – these lifestyle choices are culturally aspirational but also expensive and too often only the well-off can afford them.

The second stage of the changes are rooted in the food system becoming more industrial and concentrated so that processed foods and fast food become more affordable to all. Fast food is “fast,”

Food and Health Policy, Table 1 Food and Health Policy

	“Old” food poverty	“New” food poverty
<i>Availability</i>	Lack of food	Overabundance of processed foods
<i>Nutrition problem</i>	Undernutrition	High calorie intake and overall lack of balance and possible micronutrient deficiency
<i>Specific groups</i>	The urban poor, the “indigent,” and those who are unemployed	The same but with the addition of the working poor
<i>Nutrient profile</i>	Nutrient light	Energy/calorie dense
<i>Nutrition problem</i>	Undernutrition	Lack of balance
<i>Meal occasions</i>	Few	Continual “grazing”
<i>Food expenditure</i>	High % of household spending	Low % of household spending
<i>Price implications</i>	Absolute cost of food	Relative cost of food
<i>Social implication</i>	Removal from the norm	Social and cultural isolation
<i>Work</i>	Manual	Sedentary
<i>Easiest mode of access</i>	Walk or bike	Car
<i>Fuel</i>	Food	Fossil fuel
<i>Drink</i>	Water	Carbonated drinks
<i>Price pressures</i>	Cost of food	Cost of food relative to other demands, e.g., transport and housing
<i>Appearance</i>	Thinness	Obesity
<i>Fantasy role model</i>	Plump/fat royalty	Thin celebrities
<i>Disease patterns</i>	Diseases of “want” characterized by undernutrition	Diseases of “want” and affluence occur side by side

Adapted from Lang et al. (2009) (see also Food and Class)

thanks to modern technology and suits modern lifestyles and in many instances a viable option for those on low incomes (the Big Mac index is an indicator of how much time you have to work to afford a Big Mac, see <http://www.bigmacindex>.

org/). In fact, the use of takeaway and fast food (or street food) often becomes an important money and labor-saving mechanism for many who are engaged in piecemeal work.

At the latter stage of the transition, the rich classes return to eating more basic foods due to the health implications (see Population Growth; Slow Food). The dietary impacts of such moves, for the poor, are an increase in the fat, salt, and sugar content of these foods with possible long-term consequences for health burdens. Food or nutrition policy that focuses on one aspect is bound to be only partial in its scope and effectiveness. Obesity and coronary heart disease (CHD) have, until relatively recently, been viewed as a diseases of affluence/food choice and less of a problem in developing countries than in rich, industrialized ones. This is no longer true (see Caballero and Popkin 2002; Egger and Swinburn 2010). CHD and some food-related cancers (e.g., bowel) are on the increase in developing countries, where the more affluent social groups are tending towards a more “western” lifestyle – eating different foods, taking less exercise, and not just aspiring to, but achieving, western patterns of consumption. In developing countries, obesity now exists alongside more traditional problems of undernutrition.

The modern globalization process means that many of these changes are now occurring in the space of single years as opposed to decades (see Population Growth). The consequence is that the chronic and acute diseases and problems associated with food occur side by side as opposed to occurring temporally or sequentially. So the behaviors associated with poverty are played out by a section of the population, while another section indulges.

Allied to this is the concept of relative poverty, where the shifts reflect both changing lifestyle practices and cultural norms and not simply the amount of food. Food poverty is relative, in that it is dependant on the standards in a society, and people define their cultural needs relative to the population standard; in many developed countries not being able to afford meat or being able to eat out are now considered part of the measures of food insecurity/poverty. The term “socially

acceptable ways” is often included in definitions of food poverty/security; this could, for example, be taken to mean that even if an individual would get their nutrient requirement from a source such as a food charity that it is unacceptable if the majority of their contemporaries are able to afford a healthy diet and shop at supermarkets. A definition of food security is “Access to enough food for an active, healthy life; at minimum, includes the ready availability of nutritionally adequate and safe foods and an ensured ability to acquire acceptable foods in socially acceptable ways” (included in Troy et al. 2011). The recent US Institute of Medicine report provides definitions of food security, high food security, low food security, food insufficiency, and hunger. Troy et al. (2011, pp. 2–3) define very low food security as:

A range of food insecurity in which households report multiple indications of food access problems, but typically report few, if any, indications of reduced food intake on the USDA survey. Households reduced the quality, variety, and desirability of their diets, but the quantity of food intake and normal eating patterns were not substantially disrupted.

This illustrates the changing nature of food insecurity/poverty. The Feeding America campaign (see <http://feedingamerica.org/>, accessed 22nd Apr 2014) reports that 37 million Americans regularly go hungry. This is alongside the problems associated with overconsumption such as obesity and related chronic diseases such as diabetes. Indeed, many of the same groups who overconsume may at different stages go hungry.

Hunger still exists in many communities, and the changing global economic crises are exacerbating this, often in new ways and groups such as migrants and the working poor. For example, migrants, in many nation states, have ambiguous status and entitlement to welfare and security benefits. The working poor are in danger as they may not be entitled to welfare and food benefits but are forced to squeeze their available income, and what is known is that spending on food is the elastic item in the budget that you can cut back on. Riches (2002) has reported similar trends in Canada.

This is equally true of the life sciences approach mentioned earlier, where the benefits will be available to those who can afford them, and they may even widen existing inequality gaps. Advances in treatment, novel foods, biotechnology, the human genome project, and epigenetics are less likely to be available to those with the most need but the least resources; this is true at both country and individual levels.

Interventions in Public Health and Obesity Prevention from Tax to Subsidy

There are clearly benefits from a globalized world. In this respect, it is important to make one crucial distinction; the association of free-market liberalization and economies based on this principle with liberal societies is at one level misleading as it is not with a straightforward relationship (Hertz 2001). Many development reports identify the Scandinavian countries among the best places to live, and many of these have barriers to food trade based on public health principles (e.g., sales tax on unhealthy foods, Sweden and its banning of advertising to children, Denmark with its ban on trans fat. Other countries such as the United Kingdom, the United States, and Australia advocate protection systems based on voluntary agreements with the food industry (Panjwani and Caraher 2014).

A report from bankers USB Warburg (2002) pointed out that health issues such as obesity are better controlled in well-regulated societies. The old public health was concerned with infrastructure and the provision of health food to people. The neoliberal economic agenda has shifted this from an emphasis on state provision to one of consumer choice. Essentially reflecting a move from the rights of citizens to one where the consumer has to exercise caution as in “caveat emptor” or buyer beware.

Caraher and Cowburn (2005) point out that interventions need to focus not just on taxation or removal of certain foods but to look to a comprehensive approach so that taxation of food high in fat, salt, and sugar is matched with subsidies on healthy options. However, given the antagonism

that and the general public and the food industry express over taxation may require a selectivist approach to its introduction. For example, focusing on children or vulnerable groups in the first instance helps win over public and political opinion. The debate should not be about whether food taxes disadvantage the poor or restrict choice but what is the part that food taxes play in any overall program of intervention. As opposed to being seen as barriers to health and growth, such interventions can be seen as contributions to long-term health and even the GDP of a country (Caraher and Carr-Hill 2007).

Food programs such as the World Food Program organized by the Food and Agricultural Organization (FAO) are moving from models of delivering food that rely on global trade to models that encourage local food production and sustainable development (Food and Agricultural Organization 1999). The new policy of enabling development fits well with Keynes’ maxim in *National Self-Sufficiency* that ideas, art, and culture should circulate freely across borders but that capital and goods should remain national. For example, in many sub-Saharan areas, the staple diet is based on the production of maize. The problem is that maize is a cash poor crop, and currently the focus is on raising the incomes of farmers by encouraging them to grow high-value crops. The tension here for food security is that such a policy leads to food becoming rivalrous in both the domains of consumption and production. Cash crops for farmers result in more money for the producer but are more expensive and possibly less nutritious and less energy dense foods (e.g., it requires 440 g of potatoes to provide the same kcal as 100 g of maize). The recirculation of money may also only occur within a select elite group and have a trickle down or diverse impact. The idea is that such goods could command a cash price locally or internationally, resulting in the flow of money to buy maize on the international market. While farmers would benefit, the community in general may suffer if the international commodities market results in the price of potatoes dropping or the price of maize rising. Such a policy based on changing local food habits also runs the danger of having to overcome cultural barriers towards food.

Such policies, outlined above, as well as being based on crops for cash (and export) are often accompanied by the removal of subsidies and support for farmers and crops. The use of subsidies and its influence on global trade can be gauged from the fact that in 1999 (Lang and Heasman 2004):

- In the UK, £76 billion was provided in support to farmers in Europe – this accounted for 49% of income per full-time farmer, which was estimated to be £11,221 per farmer.
- In New Zealand, which operates a similar scheme to Australia, the extent of support to farmers was £60 million, and this accounted for 2% of income or £660 per full-time farmer.
- In contrast, the situation in Poland was that the total subsidy was £2 billion, and this accounted for 25% of total farm income but only £660 per full-time farmer (see Lang and Heasman 2004 for a discussion of this).

Farmers sometimes change their mix of crops in response to the removal of subsidies or because of low prices for one crop, but frequently they do not or cannot. The behavior of Ethiopian farmers, decreasing the cropland they plant following a year of prices disastrously below their costs of production, is different from farmers in the United States, Canada, or Australia who are able to withstand a season or two of low prices. In return, the subsidies given to farmers in the developed world in areas such as the European Union and America result in the subsidization of cheap exports to the developed world and the undermining of local food systems.

The relationship between the level of subsidies in the European Union Common Agricultural Subsidy Program and rises in exports is clear – the subsidization of high-cost agricultural systems such as that in the European Union allows foodstuffs to be dumped on the world market and particularly the developing world (Lang and Heasman 2004). Subsidized agriculture in the developed world is often criticized as a form of protectionism. And has influences on food security both in the country of origin and the global market where it can be argued it allows unfair trade by competing

with local produce. It both externalizes the cost of “cheap” food and even exports the negative health consequences. Here can be seen the negative impacts of subsidies – increasing food prices for the consumer and more especially for the poor. In addition, subsidies may lead to increases in intensive agriculture with a subsequent impact on natural capital in terms of increased pollution.

The same argument can be made with respect to the reduction or removal of subsidies – this forces farmers to resort to more intensive farming methods with subsequent impacts on the natural environment and the health of local farming communities as well as the physical and financial infrastructures. On the other hand, there can be benefits, depending on how subsidy policies are set out and conceived. Currently, there are few food policies which focus on using subsidies as means of producing more healthy food in line with nutrition guidelines.

The current restructuring of the Common Agricultural Programme (CAP) in Europe heralds a return to the social roots of the European Common Market (Garzon 2006). Its origins lie in equalizing the income differential between rural and urban areas with the additional purpose of keeping farmers and communities on the land and encourage environmental stewardship and livelihoods. In addition within current developments, there is an attempt to divert subsidies from large landowners and companies to smaller units. Such an approach recognizes the importance of agriculture to society and in helping create urban/rural links, harking back to the original intentions of the Treaty of Rome in 1957 (Garzon 2006).

In the United Kingdom/Europe and the United States, the subsidy program leads to support for the growing and production of unhealthy foodstuffs, the surplus of which often finds its way onto the global market and contributes to the nutrition transition. This often results in an increase in fat and processed food in the developing world.

The consequences of these moves are that those who produce cheap local food are themselves trapped in a cycle of food insecurity. This policy of encouraging development through growth appears to offer the benefits of creating less

dependency and of encouraging both money and goods to circulate locally. This is in contrast to traditional models of food aid which were vertically based, relying on food being bought on the world market and then brought across national borders and distributed to local distribution points. Yet both come with their problems.

Unbridled choice as noted in the previous section is not good for health as individuals tend to revert to choosing what they like a lot and if left to their devices feast every day. This is especially true for young people where habits are set early and become the templates for food behavior in later life.

Discussion

Why is all this important? It is important because the lessons of the past are not being addressed, and this new generation of food problems are presented as if they were something new, whereas in fact they are part of a longer tradition originating in the first nation states and trade as was seen in the Columbian Exchange following the discovery of the Americas by Columbus. The west gained the potato/tomatoes/maize, new colonies for food production, and in turn the Americas got communicable diseases which in some instances decimated populations. Now chronic diseases such as heart disease and cancer are crossing boundaries in following the food trade. Albritton (2009) argues that capitalism creates hunger and obesity and that these dialectics of the new poverty are the result of control of the food system by a small number of global companies right through the food chain. This is among the reasons why many embrace alternative food networks and supply systems as an attempt to escape such control by outside factors; a lack of trust in the conventional food system drives people towards a sense of localism (Morgan et al. 2006). This move away from direct action can also be seen as a failure of food policy, a failure to engage and to understand the dynamics of modern food policy and capitalism. While the new generation of nongovernment organizations (such as Greenpeace and Friends of the Earth) are developing sophisticated ways of

dealing with the new global order, other activists are becoming disenchanted and seeking ways of direct action or, more increasingly, indirect action by opting out of the system. Those protestors, who through their violence gain media attention, may be less concerned with the issues of reform of the system than with its overthrow. They may, in fact, be diverting attention from the problems of poverty and access. The individual protest is devoid of meaning beyond the community in which it happens (Caraher 2003).

Belasco (2007) noted that the instigators of the “new austerity” movement the alternative food networks often had their roots in “oppositional” politics and this can be harnessed to develop what Thompson (1993) termed the moral economy of the mob – that is, a concern with higher level elements beyond the individual. However, there is the concomitant danger of extending this model of self-help. Encouraging people to act and then ‘blaming’ them when their material and financial circumstances work against them making such changes. Or blaming them when their individual changes do not add up to a mass change (Caraher 2003).

This new protest movement may involve others in simply getting on with growing and supplying food to themselves, their families, and neighborhoods. Some of this can happen at a structural level, whether at state or regional points. Toronto stands out as an example of a citywide food policy, which in recent times has sought to influence its own food supply hinterland and foodshed (Straessle 2007; Lister 2007). The difference between the Toronto experience and that of other alternative food movements is that food policy is embedded in the systems of the state. This of course brings with it its own disadvantages but does include the possibility of more structural and lasting changes in terms of what it can influence. Also the Toronto experience is one of linking the ecological aspects of food production with reductions in food poverty.

The current focus on food as a green issue hides the poverty of many who are not able to access or afford food and may also misunderstand the cultural aspects of food and its social significance (Caraher and Reynolds 2009).

The challenge for these new networks is to broaden their scope by adopting a broader approach to include lobbying, campaigning beyond members' individual interests and include a specific approach to addressing inequality and inclusiveness.

With the popularity of the new austerity movement (see Slow Food), there is a danger in taking the words of the American philosopher Aldo Leopold (1996) at face value when he said there are spiritual dangers in not owning a farm; the first is to suppose that “breakfast comes from the grocery store” and the second that “heat comes from the furnace.” The thrust of this argument is alluring but worrying as it runs the risk of victim blaming and of allowing the behaviors to be closely associated with values that assume self-help is the answer. All of the above point to a need for food policy which integrates the issues of food growing, production, processing, and consumption of food. While we may want to define and measure the problem this should not blind us to the necessity for action to tackle the problem, justice needs to be seen to be done. As Amartya Sen (2009) argues in his book ‘The Idea of Justice’ we need to make the world less unjust by actions and not simply seek to articulate a grand theory of justice. Therefore we need research which shows us the way forward in tackling problems and not just describe them.

Summary

The thrust of the Aldo Leopold argument is alluring but worrying as it runs the risk of victim blaming and of allowing the behaviors to be closely associated with moral values and of locating food policy as simply about facilitating individual decisions to behave morally. These, while useful, do not fundamentally change the conditions or circumstances in which people live, and for those who are food insecure or living in food poverty, they will in most cases introduce an extra burden. The Via Campesina movement from the developing world provides one model where the welfare of food is linked to the green issues of sustainability and concern for the environment (see <http://viacampesina.org/en/>), but the roots of this movement are in

oppositional politics and of providing a voice for the poor and disenfranchised. Any food policy needs to incorporate all these elements and of creating supportive environments to health and the environment through regulation and education.

The tension for food policies is to find a space between the issue of protecting the environment and contributing to health while providing a just and fair food system for citizens. Often this means finding solutions to the current dominant vertical global food supply system by looking at domestic production with more than an economic lens. More and more, this perspective is finding a voice in the growing food sovereignty movement (see Wittman et al. 2011 for a perspective on this and also Food and Agricultural Trade and National Sovereignty).

Introduction

Life chances refer to the opportunities each individual has to improve upon his or her quality of life and are generally correlated to the individual's social situation. Traditionally, life chances has been related to lifestyle choices and the distribution of rewards, however has more recently been used within a social justice perspective informing the question of capabilities and inequalities between social categories (Manuel 2006).

The world is now a place where opulence and destitution are the lived realities of certain groups. Sen argues that this opulence is unprecedented, to the extent that it would have been challenging to imagine a century or two ago. Simultaneously,

there is “deprivation, destitution and oppression” (Sen 2001, p. xi). Brown and von Braun state that roughly 80% of the world's 1.2 billion poor are dependent on agriculture for their survival (Brown and von Braun 2003, p. 1040). The chance of belonging to this group of 1.2 billion people is pervasively determined by “the chance event of being born in one nation rather than another” (Nussbaum 2006, p. 224). Resolving this inequality is not a simple task. Hobbs argues that “global inequity is the essential challenge facing the planet today” (Hobbs 2006, p. 165).

Historical and contemporary ethical perspectives on food production, distribution, and consumption do not always adequately address the issue of vulnerability and limited life chances. This entry uses recent historical approaches to the ethics of food systems as a lens to explore the complexities of addressing the limited life chances of certain groups of men, women, and children in a globalized world. The entry will use a case study to highlight the intersections and divergences between dialogue concerning the ethics of food production, distribution, and consumption and the ethics of addressing limited life chances for vulnerable groups.

Food production systems have been defined as the combined elements of land, labor, capital, technology, the market, and the institutions that govern their allocation (Brown and von Braun 2003, p. 1040). The application of the definition of “consumption” to food can be undertaken narrowly, i.e., “to eat or drink,” or can be applied more broadly to include definitions such as “wasteful,” “squander,” “absorb,” or “to use up” or “expend” (Collins English Dictionary 2003).

This entry will use the case of the cocoa bean to discuss ethical perspectives and the adequate consideration of the limited life chances of vulnerable groups. The entry will provide a brief background on the history of food ethics in order to situate the ethical concerns raised regarding the food supply chain of chocolate. This example will then be used as a case study to discuss the complexities of a number of ethical perspectives and to argue for systemic ethical perspectives in order to address vulnerability and limited life chances.

Illbery's Place, Process, and Product

The distancing of people from sites of food production began prior to and throughout the Industrial Revolution (1750–1900) when, in most of Europe, the countryside was depopulated through the urbanization of the new working classes (see Goodman 2009, p. 10; Campbell 2006, p. 119). This irreversibly altered human relations with food (Campbell 2006, p. 119) and since that time, food production systems have become increasingly globalized, creating complex “farm to table” linkages (Brown and von Braun 2003, p. 1040).

In the late 1980s to the mid-2000s, a wide range of microbiological, contaminants, and animal disease-related food scares were reported throughout the European Union (Knowles et al. 2007), inciting a “crisis of trust” among consumers concerning large-scale agriculture and nameless and faceless food (Goodman 2009, p. 3). The food scares corresponded with reports regarding the use of child slave labor in West Africa's cocoa farms and the distance between the “farm and table” in mainstream food provisioning became a source of concern for the “moral” consumer.

Vulnerability and the Chocolate Supply Chain

In the late 1990s and early 2000s, numerous reports and newspaper articles tracing the use of child slave labor to chocolate products in the international market confronted consumers in the West. In 1999 the United States Department of State report cited an Ivorian newspaper reporting the widespread practice of importing migrant child laborers from Mali to work on plantations (USDOS 1999). This was followed by a 2001 International Labor Organization report that the trafficking of children is widespread in West Africa. By 2002 these findings were quantified in a joint report by the ILO and the International Institute of Tropical Agriculture stating that an estimated 284,000 children in cocoa farms in West Africa were “either involved in hazardous work, unprotected or unfree, or have been trafficked” (IITA 2002).

During this time, the news spread quickly through the international media, and commentators did not miss the paradoxical nature of the West's sweet pleasure, being produced on the backs of children in slave-like conditions.

An English newspaper *The Express* reported on a documentary produced by award-winning Brian Woods and Kate Blewett, stating that “Chocolate, it seems, carries modern-day slavery into our homes” (Wolfe and Holdstock 2005). Woods was quoted in UK's *The Guardian* on September 28, 2000 as saying “We wanted a way of bringing it home to people in the West and not letting it be something people could watch and go ‘Isn't it terrible what people in far-off lands do to other people in far-off lands’” (Wolfe and Holdstock 2005). In the United States Knight Ridder Newspapers profiled children who were cocoa farm slaves and reported on a farmer who had been prosecuted in Cote d'Ivoire for mistreating 19 migrant child workers (Knight Ridder/Tribune Business News 2001).

Shifts in Ethical Considerations Concerning Food Systems

A fundamental shift in the approach to ethics in food systems followed. Korthals argues (25) that for a long time, the ethics of food was predominantly concerned with food security, focusing on the ethics of distribution and misdistribution and on what might be considered as fair distribution. Though the problematic use of child labor in food production had been established for almost a century, with the 1917 US National Child Labor Committee producing the “Children in Food Production” report, the fundamental shift in ethical perspectives relating to food did not take place for about 60 years. The fundamental shift in the approach to ethics in food systems was representative of “...momentous shifts across the global and national landscapes” (Sassen 2000).

During the late 1980s and 1990s, with the collapse of Soviet-style communism in Eastern Europe, the concentration of power elites in the

global North and with the rapid expansion of global flows of trade, “globalization” as both a process and a political ideology rapidly became “decontested in public discourse” (Steger 2005, p. 14). By the mid-1990s the whole proportions of the global population, within both the global North and the global South, had accepted and internalized ideologies supporting the deregulation of markets, the liberalization of trade, and the privatization of the state (Steger 2005, p. 14).

Simultaneously, momentous legislative shifts were taking place. The 1917 US National Child Labor Committee Report established the link between the ethics of food production and child labor, formulating suggestions for the control and supervision of children in work, in order to safeguard American children from loss of education, overwork, or neglect (National Child Labor Committee 1917, p. 3). This was followed by international legal treaties, similarly attempting to protect children from the worst forms of child labor, including the 1919 Minimum Age (Industry) Convention No 5, which established 14 years as the minimum age for children to be employed in industry and was ratified by 72 countries. In 1966 the International Covenant on Economic, Social, and Cultural Rights enjoined state parties to protect young people from economic exploitation and from employment in work harmful to morals, health, or life. The 1973 International Labor Organization’s Minimum Age Convention No. 138 obliged member states to pursue a national policy to ensure the effective abolition of child labor and establish that no child can be employed in any economic sector below the age designated for the completion of compulsory schooling. However, it was only the 1989 Convention on the Rights of the Child that recognized the *right* of children to be protected from work that threatens their health, education, or development (Article 32). Prior to the Convention on the Rights of the Child, child laborers were objects of charity or humanitarian concern; they were not considered to have legal rights (United Nation’s Children’s Fund 1997, p. 17). Consumers and civil society in the United States and Europe responded to this new knowledge with demands for action (World Vision 2011, p. 5).

The Rise of the “Worried Well”

The 1970s and 1980s saw the introduction of ethical considerations regarding consumption. At inception, consumption ethics primarily focused on environmental campaigns to promote considerations of personal responsibilities within everyday lives (Martens and Spaargaren 2005). However, born out of this new politic of consumption, a shift from production politics to consumption politics leads to the emergence of new social movements, informed by reflexive modernization (Campbell 2006, p. 126). Launched by three leading European sociologists, Giddens, Beck, and Lash published “Reflexive Modernization, Politics, Tradition and Aesthetics in the Modern Social Order” in 1994 (Beck et al. 1994), directing attention to the process of modernity itself. Reflexive Modernization called for a reevaluation of the resource base that is already in existence, rather than the use of science and technology to expand the resource base.

This leads to a renewed emphasis on social justice in food production and consumption and a focus on “short food supply chains.” Localized organic quality food networks were integral in the strategy to restructure the productivist model of the post WWII agricultural settlement (Goodman 2009). Critical social analysis on alternative food pathways renewed the emphasis on social justice in food production and consumption practices. Drawing on the work of Foucault, Beck, Giddens, and Harvey, the alternative model suggested that Western societies had moved from a state of government to governance (Campbell 2006, p. 118), marking the move of individuals from citizens to consumers. This shift is observable in one of the first reports on the genetic modification of food products, the 1994 Polkinghorne report. Within the report food is framed as “politically and ideologically neutral” (Korthals).

The only ethical issue widely considered concerning food previously was the misdistribution of food, not issues of production and consumption. Raising conflicting perspectives regarding the sovereignty of the consumer, alternative, short, and slow food pathways were demanded by the “ethical consumer.”

The Ethical Consumer and the Chocolate Supply Chain

Within West Africa, multinational cocoa-processing and chocolate-producing companies blamed West African governments for the use of child slave labor in the chocolate supply chain, stating that the primary responsibility for enforcing human rights was with governments, charging them to “investigate and eradicate any criminal child labor activity” (see Schrage and Ewing (2005), p. 105). Blame was returned to the multinationals by the West African governments (particularly the Ivory Coast and Ghana as the largest cocoa producers), accusing the industry of earning billions off the labor of children (World Vision 2011, p. 5).

Industry giants initially denied knowledge of child labor in their supply chains and then argued that the task of guaranteeing working practices on every farm was too complex (Schrage and Ewing 2005, p. 104). Cocoa brands were only spurred to action in response to media attention detrimental to their branding (Schrage and Ewing 2005, p. 104) and the serious consideration given to regulating “child-labor-free” cocoa labeling by US politicians (World Vision 2011, p. 8). In order to avoid regulation yet respond to calls for action by consumers, an agreement for cocoa processors and the chocolate industry to collaborate voluntarily became appealing to industry giants. The Cocoa Industry Protocol (often cited as the Harkin-Engel Protocol) laid out a series of date-specific action to work towards eliminating the worst forms of child labor (WFCL) from supply chains and was agreed to by major cocoa and chocolate companies, the US government, and West African governments in late 2001 (World Vision 2011, p. 8).

Notably, the Cocoa Industry Protocol referenced major international legislative frameworks including the International Labor Convention No. 182 and the International Labor Organization Convention No. 29, collectively prohibiting the Worst forms of child labor and forced or compulsory labor (Schrage and Ewing 2005, p. 106).

Confidence in the Harkin-Engel Protocol began to diminish in 2008 as the process failed to deliver on the Protocol’s core objective of

creating and implementing a public standard and certification process to provide consumers with a “guarantee” on “cocoa free of the worst forms of child labor” (World Vision 2011, pp. 5–6). Agreement on a public standard was never reached, and rather than providing absolute certification, a continuous improvement system was produced.

In February 2008 Fortune reported that many aid groups share the opinion that the provisions of the Cocoa Protocol have still not been met, with the situation worsening in the Ivory Coast between 2002 and 2004 when civil war gripped the country and “blood chocolate” was said to be resourcing armed groups (Parenti 2008). Even the Executive Director of the International Cocoa Initiative admitted “We’ve not yet had a significant effect, but it’s a journey” (Parenti 2008).

During this period, “fair trade” expanded from an organized social movement to a market-based approach, aiming to assist producers in developing countries to establish better trading conditions and aiming to promote sustainability. The initiative/s advocated higher export prices and higher social and environmental standards. In 1988 the first Fairtrade label was launched under a Dutch development agency initiative and in the late 1980s and early 1990s the initiative was replicated in other markets in Europe and North America. The first Fairtrade certified product was Green and Black’s Maya Gold Chocolate and was made with cocoa from Belize, in 1994, just a few years prior to the news of child labor, slavery, and human trafficking in West Africa’s cocoa plantations. In 1997 the Fairtrade Labeling Organizations International was established in order to incorporate all labeling initiatives into one worldwide standard and certification. By 1999, the Fairtrade labeling system was positioned perfectly to respond to the reports regarding the chocolate industry’s supply chain. By 2001 the retail value of annual Fairtrade sales reached 30 million pounds and 290 million pounds by 2006 and 500 million pounds by 2007 (Fairtrade UK). In the 2007 annual report, Fairtrade Labeling Organizations International estimated that over 7.5 million producers and their families benefited from fair trade funded infrastructure, technical

assistance, and community development projects (Fairtrade Labeling Organizations International 2007).

The Worried Well

From the early 1980s, food has become increasingly political, whereby the “worried well” pursue alternative food pathways and have revitalized regional gastronomic interest in order to fulfill the moral obligation of personal responsibilities within everyday lives. Along with the politicization of food became the morality of food, leading to the performance of food (Goodman et al. 2010).

Simplistic dichotomies of food categories were constructed, including “. . . fast and slow, reflexive and compulsive, fat and thin, and, hence, good and bad” (Guthman 2002). Fast food was bad, reflexive food good, and fat food best avoided in order to fulfill the role of the ethical consumer. However, predominantly the categorization of the “ethical consumer” has been typically filled by the white middle classed, “worried well,” rich in both economic and cultural capital (Goodman 2009, p. 2). Higher-income consumers with the means have been afforded the luxury to opt out from mainstream food networks, in a move away from “placeless and faceless” foods (Goodman 2009, p. 3). The class and gender dimensions of slow and local food production highlight an ethical perspective reliant on the gendered division of labor, simplistic portrayals of the “good” and the “bad,” and a return to cooperating with the “old enemies” of supermarkets and multinationals.

The risk being that when food is categorized into binary forms of “good” and “bad,” power asymmetries between actors in the food production and consumption network becomes obscured from view. Guthman outlines the complicated ethical considerations not only in conventional food but also in ethical alternatives. The tremendous amount of unpaid feminized labor involved in slow food and the service the fast food industry provides to women who work outside the home remain problematic and unresolved ethical considerations (Guthman 2002, pp. 55–56). Within the alternative model, consumers emerge as

private and passive rather than being “eminently social, relational and active” (Goodman 2009, p. 17).

The crisis of confidence in mass-produced “placeless and faceless” foods provided a site of resistance against the mainstream food system; however, Goodman argues that alternative food networks have become commodified. These sites of resistance became mainstreamed, and in 2009 the UK multinationals held a 75% share of sales of organic products (Goodman 2009, p. 22).

Advocating for further analysis into power asymmetries between actors in the value chain, Goodman argues that though short food pathways might expose the processes of production, they fail to expose the *social relations* underpinning processes of production (Goodman 2009, p. 22).

Summary

The distancing of people from sites of food production began prior to and throughout the Industrial Revolution and has irreversibly altered human relations with food. Ethical perspectives that have resulted in alternative food pathways fail to address the “unprecedented opulence” and the “remarkable deprivation, destitution, and oppression” in the modern world brought about through globalization. Alternative food pathways rely on voluntary personal moral performances that address consumption only in the narrow terms, rather than the broad sense of “wastefulness,” “squandering,” “absorbing,” or “using up or “expending.” Shorter “farm to table” food supply chains brought about through the performance of morality by the ethical consumer do not sufficiently address the economic vulnerabilities of the working class and the gendered division of labor assumed through slow food preparation or ease the burden of the double day for the world’s working women.

Essentially, current approaches to food ethics raise serious concerns about the extent to which voluntary ethical consumption approaches can confront the extreme socioeconomic and development inequalities that are “. . . the essential challenge facing the planet today” (Hobbs 2006,

p. 165). Organized social movements, such as “fair trade” labeling, have moved to market-based approaches that, while promoting sustainability, do not interrogate the power asymmetries that have taken hold in the globalized era. These power asymmetries function within networks of global flows, rather than as linear chains of sequenced events (following Appadurai 1996).

Goodman et al. argue that the idea of an “ethical foodscape” can be added to the “ethnoscapes, mediascapes, technoscapes, financescapes, and ideoscapes” that Appadurai argues make up global cultural flows. Conceptualizing food ethics within this network of flows provides a more systemic way of engaging critically with the “...processes, politics, spaces, and places of the praxis of ethical relationship embedded and produced in and through the provisioning of food” (Goodman et al. 2010).

Food ethics must address the economic, political, environmental, and physical vulnerabilities that result in limited life chances.

Introduction

Food and place are linked at a basic level, for food must be produced somewhere, and consumed in the same place, or circulated for consumption elsewhere. However, this basic process becomes entangled in judgments about whether it was produced in the appropriate location and manner, if it is being consumed in a culturally sanctioned way, and whether the “right” inhabitants of a place are consuming it. Furthermore, the contemporary world is organized around nation-states, which has given rise to national eating cultures. These national practices coexist with more global eating phenomena, be they long standing such as the widespread consumption of sugar or more recent fast food phenomena like McDonaldization.

The concept of space spans many disciplines and goes beyond a reference to a physical location. Space can be physical, subjective, or affective; it can refer to a geographical location or be a way to speak of mental and emotional landscapes. Economic systems change the way spaces look and are used by humans. Abstract anonymous space can become a place, imbued with meaning for the user. Henri Lefebvre, one of the leading theorists of space, argues that every society or culture is generative of spatial practices, but that the practices themselves are generative of space.

Space is both a launching pad for action and a framework in which to act. Scholars of space have argued that if reality consists of time and space, too much attention has gone to thinking about time. The main framing device to understand the world has been processual – what happened when, how it was affected by earlier events, and how it might impact the future. On the other hand, how human experience is spatialized and the ways in which spatial arrangements both enable and constrain people’s lives have received comparatively less attention.

Space is an analytical category to think about the ways in which people organize, produce, and make sense of the foods around them. Space is an entry point to think about how flavors and regions come together, how people evaluate those connections, who benefits and who loses from the spatial arrangements under which foods are produced, and how capitalist practices generate spatial arrangements and their resulting inequities. Space is a lens with which to analyze a wide range of phenomena involving food and to think of the ways in which power operates through food networks. In particular, the spatialization of power and its effects opens up ways of thinking about ethics, justice, and food.

This entry touches on four aspects of space and its relationship to food. First is a discussion of national cuisines, which is followed by a consideration of political economy and how capitalism intersects with food and space. Third is the concept of terroir, which is used as an expression of how taste and place come together in a product. Finally, the entry ends with an analysis of food smells and how they encode places.

National Cuisines

The idea of a national cuisine is one way in which place and taste become entwined and projected onto a geographical location. Scholars have debated whether national cuisines exist, if they are useful categories of analysis and how they come about. One of the key considerations in thinking about national cuisines is not only what

they consist of but also what they leave out. The modern system of nation-states is predicated upon what Benedict Anderson called "Imagined Communities." These are groups of people that, through various means, feel part of a larger whole that is deemed a country. A similar act of imagination is required to frame food practices as a national cuisine, and this process runs the risk of obscuring or neglecting the multiple foodways that already exist in a country. This privileging can be part of a process where one group, be it ethnic, class based, or otherwise, asserts control of the nation. Scholars need to carefully analyze the power differentials at play in the growth of national cuisines and how these are mapped onto the geographical space of the nation.

There are several works that trace how national cuisines come into being. Katarzyna Cwiertka (2006) looked at the case of Japan and shows that two big moments in the country's political history affected the growth of a national repertoire of food. Japan broke in the nineteenth century several centuries of relative seclusion from the rest of the world and embraced western foods. In particular, the state encouraged the consumption of beef and dairy in greater quantities because it was believed that Western bodies grew strong because of them. Military catering and World War II also had an impact on the national diet; prior to militarization, people mostly ate regional specialties, but the army brought people from all parts of the country together and supplied them with the same food. The distribution networks, as well as the tastes for certain foods that ensued, helped to solidify national eating practices that continued after the war ended. The case of Japan shows that what are considered national eating practices can go hand in hand with major historical developments such as militarism.

The nation-state can be involved in more subtle attempts at creating dispositions toward certain foods among its citizenry. The French government, for example, has sponsored tastings designed to teach adults and children to appreciate the work of French food artisans, such as wines or chocolates, in contrast to the mass-produced goods that circulate in the global economy (Terrio 2000).

Scholars of globalization call attention to how national cuisines emerge in the space between global and local. Richard Wilk's (2006) work on Belize argues that pitting globalization against local eating practices is a misguided approach. Rather, eating practices are both local and global at the same time; it is in the space between an abstract globalized food culture and local practices that national eating cultures emerge. Watson's (2006) edited volume on how McDonald's is viewed across East Asia makes a similar point and argues that globalized foodways do not automatically displace local eating cultures. Rather, they are folded into local understandings about food, albeit this does not mean that there are no power differentials in how the encounter occurs.

One way in which national cuisines are codified is through cookbooks, and Arjun Appadurai's (1988) work on cookbooks in India illustrates some of the dynamics at play. Appadurai argues that the spread of cookbooks presupposes the existence of print media and a common language within the nation. In India, English acted as a lingua franca whereby cookbooks acted figuratively to present women of one group to another across ethnic lines and facilitated the exchange of flavor combinations and eating practices that contributed to an emerging sense of Indian cuisine.

Sidney Mintz (1997), on the other hand, has argued that a national cuisine is an artifice. It is constructed out of the foodways of people who live inside a country, but that these are regional and not national practices. Regional cuisines are the flavors not of a country, but of a place. The borders are not politically drawn, but are rather social borders of inclusion and exclusion. Mintz distinguishes between cuisines that are eaten regularly by the members of a group, and "haute cuisine," which he argues, is tied to the elites and can more easily be called upon to signify a national practice. Nonetheless, a cuisine for him is something that people eat on a regular basis and are familiar with, and these practices are best understood as regional and not national.

Research in this area points to the many ways in which national eating cultures emerge and change over time. They are affected by

globalizing forces dating back sometimes hundreds of years and involve a negotiation of class and ethnic lines. A central question is how the image of the nation can be mobilized so that people eat and come to like certain products and how foods can be used as markers of inside and outside status. Space, eating, and national cuisines can be sources of identity formation but conversely can place people outside the boundaries of the group. National spaces are a defining feature of the contemporary world, but that does not mean that national cuisines fit neatly into each political entity. Scholars who research these processes pay special attention to the power-laden processes that lead to food practices to be labeled as national, but keep in mind that these are contingent processes that need to be treated as such and not as natural categories of analysis.

Political Economy

In order to study how politico-economic arrangements are spatialized, scholars often look at commodity chains. The study of commodity chains highlights the ethical questions that emerge from processes of capitalist expansion and the food products carried with them. Sidney Mintz's (1985) work on the globalization of sugar is a classic study of how power and capitalism act through commodity chains. Mintz argues that humans have a biological craving for sweetness, but this alone does not explain why sugar became the sweetener of choice in the British colonial empire. If people simply like sweet, then any number of sweeteners could have emerged, but to explain the ascendancy of sugar, one needs to pay attention to the historical and power-laden processes that led to its prominence. He traces how sugar went from being a luxurious and rare spice enjoyed by the British upper classes to an everyday item in the British diet, a proletarian hunger killer that powered the workers of the industrial revolution. However, the ascendancy of sugar in the British diet cannot be separated from how the Caribbean agricultural sector was remade into an export platform for Britain and the use of slave labor to power it. Widespread sugar

consumption resulted in spatial arrangements that moved slave labor to the Caribbean and then sugar to Europe. It is in these movements that the workings of power become spatialized and ethical questions emerge of whether the spatial networks through which food is produced and moved are just and how they can be made more fair.

While there is much debate about what constitutes a national cuisine and its projection onto a territory, the modern state exerts a powerful influence in regulating the flow of food products in and out of its borders. The ways in which trade and food safety rules are set have powerful implications for the livelihoods of food producers around the world. The 1994 Uruguay round of trade talks that are now covered under the World Trade Organization put agricultural liberalization on the table. Nonetheless, subsidies and protection of domestic markets continue, especially among rich countries. These market distortions have had difficult implications for Southern farmers, who compete with subsidized production in the North and sometimes face restrictions for their own exports. For example, the trade in coffee beans from South to North favors the export of raw beans, which face few tariffs, but discourages the value-added step of roasting in the producing country by charging considerably higher tariffs. There is considerable debate among scholars and policy-makers whether further liberalization is a means to greater prosperity or if the flow of agricultural trade is best handled in other ways. Critics of liberalization charge that powerful multinational companies are the biggest beneficiaries of freer markets and that freer markets can result in the loss of local farmers. One alternative is the concept of food sovereignty, which argues that peoples have a right to define their own food systems in ways that are culturally and ecologically appropriate. They assert that people, and not corporations, must come first in designing food policy, even if that means curtailing freer trade.

The growth of capitalism and the trade networks associated with it are powerful ways in which politico-economic relations are spatialized. This raises ethical questions about the fairness of these networks and how they can be made more just. Scholars of space argue that capitalism

creates particular kinds of places that are amenable to capitalist accumulation. For example, large-scale monocultures are places where agricultural land is turned into a space where the first objective is accumulation. The point of producing and moving food is to accumulate capital. Meeting the needs of people to eat is a corollary to accumulation. Proponents of this system argue that this provides the incentive to grow food in more efficient ways. Critics, however, would like to see food production change so that people and their needs, not capital accumulation, are at the core of the system. This would entail a shift in how commodity chains are spatialized and who would stand to benefit and lose from those arrangements. The intersection of capitalist forces and food commodity chains provides fertile ground to examine how capitalist relations result in spatial practices and how just they are.

Terroir

One of the key concepts scholars have examined to understand the connection between food and place is *terroir*. The concept comes from the French, and it roughly translates as the taste of place. *Terroir* encapsulates the idea that products such as wine, cheese, meats, vegetables, and others are inextricably linked to the places where they were produced. For example, a wine tastes the way it does because it was grown on a specific location that has unique environmental qualities, and it was exposed to weather patterns and agricultural practices that only occurred during that season. The wine is reflective of the unique set of circumstances that came together in its production and therefore reflects the taste of place.

There are many *terroirs* that are considered unique and provide a distinct experience or that are historically associated with a product. The Napa Valley in the United States is recognized as one of the premier wine-growing regions of North America, and some products like Roquefort cheese can only be produced in geographically delimited regions. The connection between taste and place can provide a financial premium, and many *terroirs* are administered by law under

Protected Designations of Origin (PDOs). These laws regulate naming rights and the provenance of the source ingredients. For instance, the technique to make sparkling wine has traveled far and wide, but for a wine to be called champagne, it must be made with champagne-grown grapes and produced in that region of France. Likewise, to call a cheese Parmigiano-Reggiano, the milk must be sourced from specific pastures, and the cheese must be produced according to strictly defined procedures.

Scholars such as Amy Trubek (2008) have contrasted the French model of *terroir*-based foods with an American emphasis on industrialization. She argues that food in the United States is produced primarily to be consistent and cheap, but not to be sensual and reminiscent of the place where it came from. She concludes that food localism and the “taste of place” must be further developed in the United States to counteract industrial food practices and shows an emerging sense of *terroir* in the Wisconsin cheese industry and Vermont maple syrup production.

Scholars argue about the political potential of connecting taste and place together. People supportive of these endeavors, like Elizabeth Barham (2002), argue that bringing taste and place together for the consumer may result in more enlightened eating practices. They criticize contemporary industrialized eating practices because they erase the connection between taste and place for the product. As commodity chains grow larger and more complicated, consumers only see the end product and have no access to the location and labor that went into making it. The commodity ends up being assessed and valued on its own terms, detached from its provenance. This state of affairs, they argue, is detrimental for it often fosters industrialization, homogenization, and a moral distancing between consumers and producers. The corrective to this state of affairs is to allow place to shine through in the commodity, which allows consumers and producers to come closer together. If this connection is reestablished, the hope is that consumers will choose commodities that allow for moral economies to emerge that place greater emphasis on the livelihoods of producers and that celebrate diversity in taste. The

taste of place is not a question of taste alone; taste and place become enmeshed in questions of social justice and morality.

The turn toward a moral food economy has sparked wide interest in agro-food studies, and Karl Polanyi has become a central interlocutor. Karl Polanyi argued that before the “great transformation,” economic activity was but one of many spheres that regulated the flow of social life; the economy, its rules and logics, was embedded in social relations, and economic activity was under a larger umbrella of moral codes that held society in place. For Polanyi, the great transformation signifies a shift where the economy seeks to detach from the other spheres of life and takes a life of its own – the economy disembeds from society. The logic of the economy is no longer to satisfy society’s needs, but rather to accumulate capital. Fulfilling human needs becomes a medium through which capitalist accumulation takes place, but it is not the *raison d’être* of economic activity. The changes brought about by this great transformation were both disconcerting and worrying to Polanyi, who argued that as the economy moves farther and farther away from the other spheres of social life, society will resist this tendency and attempt to re-embed it in social relations. Polanyi called this dynamic tension the “double movement.”

Scholars in agro-food studies have used the work of Polanyi to analyze the ways in which moral economies may emerge. One argument is that labels such as protected designations of origin (the legal framing of *terroir*) are examples of a double movement. The labels are examples of political activity that counteract market forces. Elizabeth Barham (2002) calls these labels “values-based labels” and argues that they return a sense of process to food commodities, connect producers and consumers, and re-embed the economy in social relations. Other scholars have looked at fair trade networks and argued that they are a new kind of commodity chain where moral economies can emerge. The fair trade label brings consumer and producer together in an alternative economy that opposes the logics of capitalist food production with its emphasis on profits and lowering costs. The taste of a fair-traded

product, be it coffee, bananas, etc., becomes inextricably linked to the moral economy in which it circulates. The hope is that consumers and producers will come together around a non-alienated food commodity that is also a force of change and sustainable development. In order to achieve that, they propose to keep the connection between food and its provenance, be that its unique *terroir* or the labor conditions under which it was produced, alive throughout the commodity’s cycle up to the consumer.

Critics of this approach, like Julie Guthman (2007), question whether it is wise to resolve these moral issues in the marketplace. To hope that consumers purchase the right kinds of products shifts responsibility away from government to those with money to spend. Instead of casting voluntary food standards as the seeds of political transformation, they argue that these labels and movements are best understood as market mechanisms. The labels are simply one more form of market differentiation and hardly pose a challenge to the overall structure of the neoliberal economy. The hope that these movements are an expression of a re-embedding of economic forces in social relations is misguided and could be politically debilitating in social policy is transferred to individual consumers in the hopes that they will make moral choices with their wallets. Instead, scholars working in this tradition would like to see a stronger role for states in implementing laws that allow these moral and fairer exchanges to take place. This is not to say that food and place should not be connected, but that this connection in and out of itself is not enough to resolve moral questions about the way food is produced, distributed, and framed for the consumer.

Questions of Smell

Food is appreciated in a multisensory way. Human taste buds are capable of detecting essential flavors like sweet, salty, or bitter, but a lot of the more nuanced sensations come from the interaction between the senses. Food is a tactile, visual, olfactory, auditory, and gustatory experience. Smell in particular plays a big role in the

experience. Food aromas tie communities together and also evoke memories. Theorists of smell, such as David Howes, argue that there is a strong relationship between smell and memory, for smells are often linked to the moments when they were first perceived and can act as triggers for those memories later on. There are several studies of immigrant communities and how familiar food smells serve as a source of nostalgia. These studies examine how people experience the evocative power of food smells and how they use them strategically to create slices of home in their new surroundings. Lisa Law (2001) looked at Filipino domestic workers in Hong Kong. On Sundays they often congregated in open plazas and appropriated them with familiar cooking smells. These aromas encoded the space around them in ways that were explicitly different from the sensory expectations they faced throughout the week when working in the homes of local Hong Kongese.

Other work in this area has looked at how food smells can be a marker for class and race. Sometimes immigrant communities have found themselves on the receiving end of discrimination based on what are perceived as “offensive” smells by the host country. One study found that realtors in New York City advised Asian immigrants to scrub their houses before potential buyers arrived, by which they meant the erasure of smells such as shrimp paste or kimchi. In contrast, the realtors suggested that they bake apple pie or bread before showing the house to encode it with smells more typically associated with home in the United States. Associations between food smells and home are not just sentimental, but are also enmeshed in racial and class politics. The smell of foods, and its associations to place, can be an entry point with which study questions of power, discrimination, and justice. Space as an analytical category looks at emotional or mental landscapes, and food smells are one way to study how these affective relations to food are spatialized. The evocative powers of smell allow it to encode places as familiar or foreign, to trigger nostalgia, and for people to deploy food smells strategically to mark the places around them.

Future Directions

Space is an emerging field in food studies. One of the key questions is how moral economies can emerge, and one suggestion has been to link food to its provenance in a tighter way. Thus, localized food practices, resurgence of farmers’ markets, connecting consumers, and producers across boundaries through labels have been examined to see if they can contribute to a moral economy. Future directions on space research need to tackle the extent to which place can be an answer to the emergence of more just eating practices.

Summary

Place is a lens with which to think about how food production and consumption is spatialized, how those spatial arrangements come to be, and who benefits and loses from them. This entry looks at national cuisines, commodity chains, terroir, and sensorial markers as ways in which food and place become intertwined and the ethical questions that arise out of it.

Food and Poverty in High Income Countries

[Food insecurity](#); [Food poverty](#); [Taste of necessity](#)

Introduction

Household income is the most important factor influencing the food that individuals and families eat. Income has both *direct* and *indirect* effects on the food people eat. Income affects eating practices directly either by putting economic limits on what a household can afford to eat or by allowing the ease and freedom to eat whatever is desired. It affects eating practices indirectly because of its influence on our tastes, preferences, and desires, which appear to be individual but are shaped by class positions shared with others. This entry considers the impact of income, and especially inadequate income, on food practices in rich, developed countries and the particular case of food insecurity, where financial resources are inadequate for a safe, healthy diet that meets personal, cultural, and religious preferences. The entry also introduces key theoretical concepts from Pierre Bourdieu to help explain the “logic”

of everyday food practices and to assist in reflexive practice in scholarship, health promotion, and public policy making.

The Impact of Household Income on Food Practices

For households that live in poverty, with not enough money for food, food is a constant source of stress and anxiety. Not having enough money for food, or worrying about not having enough, can alter the quality and quantity of food that household members are able to consume. In many English-speaking wealthy countries, such as the United States, Canada, Australia, and New Zealand, this condition is known as individual and household food insecurity. In the United Kingdom, it is also called food poverty. In the most severe cases of food insecurity, individuals may skip meals entirely, resulting in outright hunger. Food insecurity is a significant public health concern, associated with a higher risk of nutrient deficiencies and a range of health problems, including depression, diabetes, and heart disease. It is also in direct contravention of the basic human right to food for all, which is protected in several international agreements, including the *International Declaration of Human Rights (1948)*; the *International Covenant on Economic, Social and Cultural Rights (1966)*; and the *International Convention on the Rights of the Child (1989)*. In wealthy countries, the right to food is predicated on having sufficient income to purchase food in the marketplace, the usual way of obtaining food in these countries. Consequently, the right to food means that state governments have a responsibility to ensure income security policies, including adequate wages and a social safety net, that allow households to purchase adequate, safe, culturally appropriate, and nutritious food to meet daily needs.

Along with important direct effects on what people eat, income also has indirect effects, mediated through social class (Beagan et al. 2014). Indirect effects of income on food practices operate through preferences shaped by class position, that is, through income, education, and the

movement between class positions. For example, a desire to experiment and try new cuisines, foods, and recipes is associated with those who have higher levels of education and sufficient income to be able to do so. Those living on low incomes cannot afford to experiment with new foods or recipes; there is no room in the budget for any food to go to waste. Moreover, there may be little desire to try novel foods or cuisines, on the basis that such experimentation is “not for the likes of us,” or not something that “people like us” do. This can be a process of “making a virtue of necessity,” where conditions of material scarcity create a personal disposition that values what is necessary, such as frugality or the loyalty of sticking with the tried-and-true. For example, low-income households may buy only branded products, favoring more expensive products over similar “no-name” ones. This may be derived from a condition of necessity, because the branded product has a known and consistent taste that family members will be sure to eat, rather than the uncertain and unpredictable taste of a comparable “no-name” product. Consumption of highly marketed branded food products may also be a source of pride, a means of displaying loyalty, and offering a small, symbolic way to belong in our consumer society and be “normal,” doing what others do. It may also be a treat, offering an opportunity to dissociate oneself momentarily from ever-present poverty and deprivation.

In other words, the food practices of those living in poverty do not conform to a purely economic logic, at the same time that financial constraints are central by limiting the scope of purchases within economic possibility and by shaping taste and preferences through class dispositions. This entry introduces some key concepts from sociologist Pierre Bourdieu, whose book, *Distinction*, is one of the most important sociological texts of the twentieth century and is especially useful in understanding the relationship between income, class, and food practices. Sociological theory can be especially helpful in understanding the interaction of social or collective factors and individual factors influencing what people eat. In other words, it helps develop an understanding of why people located within

particular social positions (defined, e.g., by class, class trajectory, gender, and racialization) eat the way they do.

Bourdieu’s key theoretical concepts include *habitus*, *practice*, *forms of capital*, *the logic of practice*, and *distance from necessity*. Understanding that all practice, including food and eating practices, has a logic that is based in the habitus and derived from a particular social position, has ethical implications for those who study, wish to understand, and perhaps change the eating practices of those in (especially lower) class positions that are different than their own. The implications of this will be drawn out in the conclusion.

Theorizing Food Practices with Bourdieu

In his study of taste in France, *Distinction: A Social Critique of the Judgement of Taste*, Bourdieu (1984) found distinct patterns of lifestyle, manifested in tastes in art, music, food, clothing, furniture, and so on. While the particulars of Bourdieu’s analysis of 1960s France are not generalizable, many researchers have found his conceptual tools can be usefully applied to their particular empirical contexts to help us understand food practices and why people eat what they do, especially in relation to class (Beagan et al. 2014). In Bourdieu’s conceptualization, class has two main dimensions: economic capital (i.e., income and wealth) and cultural capital (such as level of education as well as other forms of knowledge). So, for example, the self-made successful business person, with large amounts of economic capital but less cultural capital, occupies a different social space and tends to have different tastes and lifestyle than, for example, a humanities professor, who has comparatively less economic capital but considerably more cultural capital. A schoolteacher may have similar economic capital as a tradesperson, but they will tend to have different tastes and lifestyles because of dissimilar amounts of cultural capital.

A third dimension of class, which also affects taste, is the trajectory through social space (i.e., upward or downward social mobility or a stable social position). Thus, someone moving (or with

ambitions to move) from a lower to higher social space may leave behind the tastes of the lower class and take on those of the higher class. Those moving downward in social space tend to be conservative and traditional in their tastes. Bourdieu found these associations between social trajectory and taste in whole groups, such as small business owners and farmers, who were slowly losing their historical status in French society.

Habitus

Why do people who occupy similar positions in social space tend to have similar tastes and thus similar lifestyles and practices? Bourdieu developed a theoretical concept, the *habitus*, to explain why. Bourdieu used the concept of the habitus to overcome dichotomies that haunt social theory, such as structure/agency and freedom/necessity. The habitus is the “sedimentation” or embodiment of social structures such as class, gender, and ethnicity within the individual. It is a set of *dispositions*, internal to the individual, which reflects external social structures and shapes how the individual perceives the world and acts in it. Although the social structures embodied in the habitus do not *determine* behavior, individuals are *pre-disposed* to act in accordance with the social structures that have shaped them, because, in effect, they carry those social structures within them. The habitus also shapes one’s expectations of the future. Once learned, the dispositions of the habitus become “second nature,” difficult to bring to consciousness and not easily changed. This is especially true of aspects of the habitus learned in childhood, such as gender identity.

Forms of Capital, Practice, and Class

Habitus has an important influence on practice, or our everyday activities, but it is not the only one. Practice is also influenced by the interaction between the habitus and different forms of capital. Bourdieu identifies four primary forms of capital: economic (money and wealth), cultural (formal and informal education), social (relationships), and symbolic (honor, prestige, or recognition). He understands economic capital as the most important form but shows how these different forms of capital can be exchanged. Social class,

in Bourdieu’s terms, reflects the total volume of capital as well as the composition of the capital (particularly economic and cultural), and social class trajectory (i.e., upward or downward movement between different classes).

Logic of Practice and Distance from Necessity

As Bourdieu (1984) explains, all practice has a logic, even practice that appears to others to be “illogical.” The logic of practice comes from social location, including class, habitus, class trajectory, and the different types and amounts of capital available. In his study of taste in France, Bourdieu found fine distinctions in the tastes of those in different social spaces; however, he also found two main opposing dispositions toward consumption, distinguished by “distance from necessity.” The consumption patterns of the working class and the poor are characterized by the “tastes of necessity,” while the consumption patterns of the middle and upper classes are characterized by the “tastes of luxury (or freedom).” The taste of necessity is a “forced choice” of being resigned to what is inevitable, produced by material conditions of low income that rule out other options. In contrast, the taste of luxury is so bound up in freedom of choice that it is difficult to imagine that others are much more constrained in their choices. The taste of luxury is derived not just from income, but also the cultural dispositions that come from being in the social space that higher levels of income allow. Thus, for example, those who have lived in poverty who move into significantly better economic circumstances may carry with them the cultural dispositions that incline them toward the taste of necessity and continue their frugal lifestyle despite their improved finances.

In Bourdieu’s study in France, the taste of necessity in food (for those with little economic or cultural capital) generally led to the consumption of salty, fatty, heavy, strong, simmered, cheap, and nourishing food. Those with significant economic and cultural capital had food tastes in opposition to the taste of necessity,

tending toward the light, refined, and delicate. Bourdieu also found differences between those who had relatively different amounts of cultural and economic capital and those who had relatively more cultural capital (i.e., education) tending toward healthier and more exotic food, especially low-cost exotic food such as that found at “hole in the wall” family-owned restaurants serving “ethnic” food. Cooking practices also differed among those with different amounts of capital and different relative amounts of economic and cultural capital.

Taste in food also depended on how different classes value the body and the effects of food on the body. While the working classes were more interested in bodily strength and thus tend to eat food that was cheap and filling, the professions were more interested in the aesthetic aspects of the body and thus tend to eat food that was healthy, light, and not fattening. Bourdieu found that the working class meal was characterized by abundance, particularly of “elastic” and inexpensive dishes and foods, such as soups, pasta, or potatoes. The “impression of abundance” was especially true for special occasions. The rituals of the meal (preparation, serving, eating, cleaning up) were marked by strong differences of social status, based on age and gender. Strict sequencing of the meal was ignored, and a freedom, which from a bourgeois perspective would be seen as disorder or slovenliness, prevailed. This freedom arose from a sense that eating is a form of compensation for the rest of life, where controls, constraints, restrictions, and necessity prevail, and that these should not be imposed on food and eating, the heart of domestic life. In contrast, the meals of the bourgeoisie, or middle class, were conducted as a social ceremony, concerned with form and a strict observance of sequence. Rigorous rules surround the meal, as with all other aspects of everyday life, an expression of a habitus of order and propriety.

Bourdieu maintains that this basic opposition between substance (food as material reality, sustaining the body and giving strength) and form (food as self-discipline to an aesthetic ideal) represents two antagonistic worldviews, divided by distance from necessity, which, as a function of

the habitus, affect all aspects of taste. Bourdieu argues that the distance from necessity divides us all, with no neutral point of view. What appears to be messy, undisciplined, and careless to some is straightforward, down-to-earth, and unpretentious to others. And what is refined and orderly to some is frivolous and pretentious, “not for the likes of us” to others.

Bourdieu’s work demonstrates that there is a “logic” to everyday practices, such as eating, which goes far beyond the practice or behavior itself but is instead embedded in a habitus which systematically reflects a set of social structures, not least of which is class. Everyday practices are generated from a system of perception and appreciation and form a particular lifestyle that is meaningful in relation to the social and material conditions in which the habitus was formed. Everyday practices follow a logic which is largely outside our consciousness and therefore difficult to describe in words. What people do in their everyday lives has more significance than they know or can say.

Food Practices in the Context of Food Insecurity

As household income declines, financial considerations become more and more important in the decisions regarding which foods are purchased and consumed, with the emphasis moving toward low-cost, filling foods that will stave off hunger. These decisions and choices are always weighed with other considerations, including personal preferences and tastes, health and nutrition, food quality and freshness, cultural and religious imperatives, convenience, cooking skills, transportation, and available storage and cooking equipment. However, as food insecurity grows, the cost of the food becomes the driving force in decision-making (Dachner et al. 2010; Power 2005). The person most responsible for food work makes most of these decisions and choices. Despite some overall progress in engaging men in housework, women are still primarily responsible for food work, especially the invisible aspects, such as menu planning and shopping lists, which

involve the weighing of the sorts of considerations described above (Beagan et al. 2014; DeVault 1991).

For food-insecure households, the stress of living in poverty and not having enough money for food can be overwhelming, especially if there are children involved. There is little-to-no relief in managing inadequate food and financial resources. The relentless nature of trying to “make do” and “make ends meet” requires significant amounts of time, work, and energy. It is not surprising that food insecurity is associated with much higher rates of depression than for the food secure population. With the exception of households on food stamps in the United States, who have some money (in the form of food stamps) that can only be spent on food, most low-income households can use money allocated for the food budget for other priorities, such as when emergencies arise or for months when there are unusually high expenses, such as when heating or cooling costs are higher than normal. In terms of budgeting, the first priority is keeping a roof over one’s head, by paying the mortgage or the rent. This is usually a fixed expense and a bill that must be paid on a regular basis. In food-insecure households, after housing costs are paid, there is usually little-to-no money left over. Money for other services and items, such as food, utilities, phone, childcare, clothing, and transportation, is juggled in a complex strategy to maximize benefit and avoid losing access to necessary services. Part of the elasticity of the food budget derives from the multiplicity of strategies that can be used to attain food and stretch food resources, or the last-ditch strategy of going hungry (Power 2005).

Food insecurity is a managed process, experienced on a continuum, from mild or marginal to moderate to severe. In households where there is marginal food insecurity, the person responsible for food provisioning (usually a woman in heterosexual households or in households with children) worries about being able to buy adequate amounts of food. In moderately food-insecure households, there are changes in the quality and quantities of food eaten, for example, substituting cheap and filling food for the food that would be

normally eaten. Finally, in severely food-insecure households, household members literally go hungry, skipping meals or going for a day or more without food (Tarasuk et al. 2013).

In households with children, the most severe form of food insecurity is characterized by children going hungry. Mothers will do almost anything to keep their children from being hungry, including going hungry themselves, sending their kids to relatives, shoplifting, prostitution, or “doing favors” for the landlord in exchange for rent reductions or groceries. In other words, not all household members experience food insecurity in the same way; the woman in the household normally bears the brunt of the strategic management of food insecurity. In households where there is intimate partner violence against women, food may act as a trigger. The woman will then prioritize the food wishes of her partner or husband, in the hope of avoiding violence. This may adversely affect her own food security and possibly her children’s. Intimate partner violence may also include financial abuse, with the man controlling all household finances and leaving the woman unable to protect herself or her children from food insecurity and hunger. Abusive partners may also use food to bribe their way back into relationships.

As food insecurity deepens, households change the type and the number of strategies used to feed themselves. Some strategies involve freeing up money for food or increasing the supply of money. These include working, perhaps in “under-the-table” jobs; giving up services, such as cable TV; selling possessions; delaying bill payments; or borrowing money from family or friends. Some strategies can only be used infrequently (e.g., a possession can only be sold once) or have a limited lifespan (e.g., one quickly runs out of friends unless loans are repaid). Strategies to acquire food include purchasing food on credit; borrowing food from friends or relatives; eating at relatives’ homes or sending the kids there to eat; sending kids to school meal programs; and obtaining food from nonconventional sources, such as food banks, dumpsters, soup kitchens, and other community food programs.

Another set of strategies revolves around the food itself, during the planning, shopping, and

cooking stages. These strategies include careful planning, looking at flyers, clipping coupons, making lists, budgeting, making food from scratch, planning to buy only what is essential or most filling, buying grocery store gift cards to save the money to buy groceries at a later date, and shopping only at discount grocery stores or greengrocers. During shopping trips, women also use multiple strategies to conserve money. These may include transportation considerations, such as coordinating a trip with someone with a car, walking one or both ways, or only buying foods that can be transported easily. Other strategies include not taking the kids on the shopping trip, sticking to a shopping list, adding up the cost as one shops, only buying foods and brands that are known and liked by the family, buying foods that provide the most value for money, buying foods on sale, buying cheaper cuts of meat, and buying in bulk when appropriate or buying small quantities to avoid waste. And finally when cooking, women will alter food preparation to “stretch” a meal (e.g., adding extra rice or potatoes to soup or stew); cook low-cost and filling meals of minimal ingredients; use canned foods; serve the higher-quality foods for the man or the children and eat less expensive foods herself; and cut portion sizes or skip a meal while others in the household eat. Most of this extra work to avoid hunger in the household is borne by women. Much of it is invisible, requiring creativity, energy, and skill. For low-income households with no access to a vehicle, there is additional physical labor to acquire food, adding to the physical, mental, and emotional stress and exhaustion.

In the context of food insecurity, one strategy that some households use is to turn to food charity, particularly food banks or food pantries. These charitable organizations offer limited amounts of food to those who qualify for their services, usually for a limited number of times a year. While food banks and food pantries allow some families to be somewhat less hungry, they have significant limitations. These include an insufficient supply of food to meet the demand; inability to meet the food preferences, religious restrictions, or health needs of clients; the nutritional inadequacy of

food packets; the instability and irregularity of volunteer labor and donations of food and money; inaccessibility of food banks and their services; the inefficiencies associated with connecting hungry people with donated food and volunteer labor; and lastly, but perhaps most importantly, the indignity of charity (Poppendieck 1998). Despite the best intentions of staff and volunteers, most people find that receiving charity is demeaning and dehumanizing, provoking feelings of shame and humiliation. Food charity is a blunt reminder to those who use the service that they are not part of mainstream society, contributing to a pervasive sense of marginalization. For these reasons, and perhaps others, most food-insecure households do not use food banks (Power 2014).

Ethical Considerations

Food insecurity raises two different ethical issues. The first is related to social justice and the ethical implications of hunger, poverty, and food insecurity in rich, industrialized countries. The second is a reflexive one and the ethical issues of researchers, academics, and students studying and trying to understand the “logic of practice” of groups of people who may occupy quite different social positions. Related to this are the ethical issues of health practitioners who want to change the eating habits of low-income people and public policy makers who are responsible for creating public policy to promote the health of all citizens.

Food insecurity has become a significant public health concern in many rich, industrialized countries. In the United States in 2011, almost 15% of households experienced some level of food insecurity, while over 12% of Canadian households were affected (Tarasuk et al. 2013). Both countries use the same questionnaire to assess household food security status, but the US approach is more restrictive in categorizing households as food insecure. This means that many more US households would be food insecure using the Canadian approach and amounts to millions and millions of people in two of the richest countries in the world who suffer food

insecurity as a result of poverty and the subsequent health consequences.

This situation is incongruent with principles of social justice and with the obligations and commitments set out under international agreements, including the *Universal Declaration of Human Rights (UDHR)* (1948); the *International Covenant on Economic, Social and Cultural Rights (ICESCR)* (1966); and the *International Convention on the Rights of the Child (ICRC)* (1989). Notably, the United States has refused to sign the ICESCR and the ICRC. But it has signed the UDHR, which specifies:

Everyone has the right to a standard of living adequate for the health and well, being of himself [sic] and his [sic] family, including food, clothing, housing and medical care and necessary social services, and the right to security in the event of unemployment, sickness, disability, widowhood, old age or other lack of livelihood in circumstances beyond his [sic] control. (United Nations 1948)

While not legally binding, the UDHR sets out a set of principles to which nations, at their best, aspire. Recently, the United Nations Special Rapporteur on the Right to Food has highlighted the growing number of national governments around the world that have implemented frameworks to progressively realize the right to food as a legal entitlement, not a charitable handout (De Schutter 2013). In wealthy countries, this means the assurance of an adequate income, derived from either employment or social supports, so that everyone can participate in normal channels of food acquisition (De Schutter 2013). Given the unprecedented wealth of the world's richest countries, growing income inequality, and the structural conditions that create the poverty that leads to food insecurity, it is time to reconsider our obligations to each other and to ensure the conditions in which all can thrive and contribute their best.

The other key ethical implication of understanding the impact of income on food practices is a reflexive one. In other words, those interested in the food and eating practices of those living on low incomes – whether student, researcher, health promoter, or policy maker – must understand that if they are occupying a different class position, the “logic” of their food practices will be different

than the logic of low-income food practices. This is not simply a matter of available economic resources. For example, while postsecondary students may be “poor” based on their income, the logic of their food practices will also be impacted by the habitus made possible by higher education, the sense of possibility that enabled them to get to a higher education institution and that unfolds with the achievement of a postsecondary diploma, and the sense of inclusion and doing something “normal” and valuable by being a student. For health promoters, the ethical responsibility is to understand that the food practices of low-income households are unlikely to change significantly without additional financial resources and to advocate on behalf of low-income clients for additional resources (see, e.g., Ontario College of Family Physicians 2013). The ethical responsibility of researchers is to research enough about participants to understand the logic of their practices and then to represent the research results in ways that are true to that understanding, allowing the reader to come to a similar conclusion.

Summary

Household income affects the logic of food practices in both direct and indirect ways, through the habitus and the resources available for purchasing food. In conditions of food insecurity, when income is inadequate to meet dietary needs and preferences, the cost of food becomes increasingly important in decision-making, overshadowing other important considerations, particularly health. Those in food-insecure households who are primarily responsible for food work try to manage food insecurity with numerous strategies that take considerable time, energy, skills, and creativity. Their creativeness and skill cannot dispel the anxiety and stress that accompanies food insecurity. The challenges they face demand understanding and respect. The existence of millions of food-insecure households in the richest countries of the world is incongruent with international standards and principles of social justice.

Food and the Avant-Garde

Introduction

Defining the avant-garde is an ongoing process in art and literary criticism and changes depending on the particular historical period and cultural sphere discussed. For the sake of this entry, the term refers to a collection of modernist artists and artistic movements who explore new frontiers, react against previous conventions and traditions, and engage in experimental work. The work of avant-garde artists and writers often responds to existing social, political, or aesthetic practices, making it particularly relevant to a study of ethics. In the Theory of the Avant-Garde, Peter Burger argued that the term was originally used to describe a combination of artistic goals and a sociopolitical agenda (Bürger 1984). More specifically, some of the ideas associated with the avant-garde that apply to a study of food include a wish to reintegrate art into the practice of everyday life, an interest and a prioritizing of the senses beyond sight and sound, a valuing process over product and nonrepresentational art over a fixed subject, and a fascination with language, the body, and consumption.

The historical avant-garde's power for social reform derived largely from its anti-institutional stance and its ability to reexamine and call into question products and forms that were taken for granted and have become routine. But as these artists were accepted into the art institution themselves (shown in museums and studied in

academia), their work was stripped of that power. This particular critic of the historical avant-garde is significant in the context of food work, since the ephemeral nature of most of this artwork serves to protect it to a certain extent against institutionalization.

This entry refers to two types of interaction between food and the avant-garde: artists who use food as a medium and employ it as way of interrogating traditional art practices and institutions as well as other social and cultural questions and chefs who create culinary work that can qualify as art, stretching our understanding of what is art and expanding the culinary field into new realms of interaction between chef and audience (essentially creating avant-garde work in the culinary field).

The entry begins with several examples of artists who can be directly linked to avant-garde related movements in some way. These artists share some of the central tenets of the historical avant-garde: the wish to step outside the art establishment, call into question traditional practices and institutions, promote art that is integrated into everyday life and materials, and promote an ideological agenda, questioning social or cultural tropes. The examples progress in a rough chronological order and focus on artists who engage food and food practices directly, as a medium, not only as a subject for visual art or poetry. The final section of the entry expands on this focus and presents the work of several modernist chefs. Exploring their work in the context of avant-garde art and as an extension of the artwork described below offers new insights into some of the problems associated with the historical avant-garde.

The Futurists

Futurism, an art movement of the historical avant-garde, produced perhaps the most well-known, influential, and food-centered work. In the second wave of the movement (from 1930), the Futurists devoted serious attention to culinary events, opened the Holy Palate restaurant in Turin (1931), and published *The Futurist Cookbook* (1932). Filippo Tommaso Marinetti published the first Futurist

Manifesto in 1909 and strove, with his fellow Italian Futurists, to “liberate language, art and life from tradition and convention” (Chamberlain 1989, p. 8). The Futurists saw art and everyday life as inseparable, and so everyday materials, like food and recipes, were a natural progression for their work. Using culinary devices and materials allowed the Futurists to engage and comment on traditional Western art practices and values, such as questioning the traditional hierarchy of the senses that prioritizes sight and sound, the concept of an art object as everlasting, and the injunction that art must never be utilitarian and must be confined to the museum and gallery space.

The Futurist Cookbook encourages Italians to abandon traditional culinary practices (pasta in particular) in favor of a new and “modern” culinary practice. It includes descriptions of several futurist banquets, theoretical thoughts on futurist perception of cooking and eating, and numerous recipes (called “formulas”) contributed by different Futurist artists. It provides a documentation of several performative and experimental dinners, but it is also an art object in itself. By taking a familiar everyday object such as a cookbook and appropriating it to deliver the futurist artistic message, Marinetti is combining several of the futurist ideals: not only the interest in everyday life as material for art but also the hybridization of different genres, the importance of the chemical senses (taste and smell), the body as a present and participant in the artwork, and the interest in technology, scientific discovery, and innovation—all of which play a part in the recipes and banquets the Futurists staged.

The Futurists had a very strong, unabashed, and political and ideological message, and *The Futurist Cookbook* expresses some fascist ideals, mostly exemplifying strong nationalist tendencies and a chauvinistic approach, advocating Italian patriotism and condemning bourgeois habits and lifestyle. The book is a poetic text that expresses both an artistic agenda and an ethical one: the Futurists wished to change the Italian persona, influencing and reshaping both Italians’ minds and their bodies. However, the cookbook remains first and foremost an artistic creation, its irony mostly apparent in the selection of clearly inedible

dishes scattered through the text, like *The Excited Pig*: “A whole salami, skinned, is served upright on a dish containing some very hot black coffee mixed with a good deal of eau de Cologne” (Fillia, in Marinetti 1989, p. 144). This and other inedible recipes serve as reminders that this “cookbook” is in fact an art object and not a kitchen manual. They force the reader to pause and consider each recipe, not take them for granted. They call into question the very nature of recipes and instructions and emphasize the need for vigilance and independent thinking (for more on the Futurist banquets see Delville 2008).

Fluxus

This multidisciplinary, international movement originated in the 1950s in Europe and the United States and continues to some degree to this day. One of the most influential forces at its inception in the United States was experimental musician John Cage, whose class on musical composition in New York in the late 1950s inspired some of the central techniques later used by Fluxus artists, like George Brecht’s *Event Score*, chance-generated poems by Jackson Mac Low, and Allen Kaprow’s *Happenings*, describing his multimedia theatrical events (Higgins 2002, pp. 46–48). Two central elements in Fluxus artists’ work were the performance event and the Flux kit. Both were based on simple, everyday actions and objects and highlight the notion of experience. Rejecting representational art and focusing on primary experience, Fluxus’s work defies fixed definitions; its central ideology is the rejection of any assigned, permanent meaning (Higgins 2002, pp. 58–59). Thus food, as a temporal medium that offers a wide range of opportunities for social interaction and immediate experience, appears often in Fluxus artists’ work. These artists include Alison Knowles (*Make a Salad*, 1962; *Make a Soup*, 1962; and *Identical Lunch*, 1967–1973), George Maciunas (*Flux banquets*, 1967–1978; *One Year*, 1973), Ben Vautier (*Flux Mystery Food*, 1963 and 1966–1967), and Daniel Spoerri (*Twenty-nine Variations on a Meal*, 1964), among others.

Daniel Spoerri’s early *Trap Paintings* literally captured remains of meals, gluing to the table’s surface, empty dishes, cutlery, and leftovers and then flipping the surface to hang vertically. These projects, created from 1960 and on, were based on an individual meal, a collaboration with other artists, or the result of banquets and dinners Spoerri staged at his Spoerri Restaurant (1968), the Eat Art Gallery (1970), and other venues around the world (Novero 2010). The *Trap Paintings* were essentially collages created by chance actions during a meal. Preserving and displaying these remains reflect Spoerri’s interest in everyday materials and in their perishable nature, reflecting similar interests of earlier avant-garde artists. Spoerri’s themed banquets and the idea of creating a working restaurant that, in addition to serving traditional German fare, also hosted guest artists as chefs were very much in the spirit of the Futurists, bringing his edible work into a real-world context. Some of Spoerri’s themed meals revolved around regional/national dishes no longer common and recognized as such in different countries, problematizing the clear definitions of a national, centralized cuisine. In this, he diverges from the Futurists and their strong nationalist agenda, questioning rather than trying to influence a national diet.

This approach to political ideology is characteristic of many more recent avant-garde artists, who prefer to call into question or problematize existing sociopolitical ideologies, rather than a prescribe one.

Some Fluxus artists’ work involved a reframing of everyday acts of the artists themselves as art events, like **Ben Vautier’s** *Flux Mystery Food*, which entailed purchasing unlabeled cans of identical size and eating whatever was inside them (1963). A later variation included replacing the labels with ones that read *Flux Mystery Food* (1967). Another example is **Alison Knowles’s** *Identical Lunch* (1967–1973), in which the artist consumed the exact same lunch every day, over a period of several years, at the same time and at the same place: tuna sandwich on whole-wheat bread with soup or buttermilk at Riss restaurant in Chelsea (Higgins 2002; Novero 2010).

Even though Fluxus artists are obviously interested in taste and smell, many of these works focus on a shared, communal experience, on language and representation, and on classification and organization rather than on gastronomy (Novero 2010). Unlike the Futurists' interest in creating innovative work on the plate, most Fluxus artists explore eating rituals and mine food for its ability to call into question the Western hierarchy of the senses and present art as a total experience, free of fixed definitions. It highlights these artists' interest in creating multisensory experiences that frame "pieces" of everyday life and draw our attention to them, allowing that everything is material for art. This inversion of accepted Western cultural hierarchies and questioning of common perceptions extends beyond the art world into other social and cultural realms of experience. Subverting the art institution implies the suspect nature of other institutions. By calling into question common perceptions regarding the value system and hierarchies within the art system, these artists encourage the audience to question the status of Western culture, the division of gender roles, or other sociopolitical classifications.

Carolee Schneemann was connected with several Fluxus artists and events, and her work in live performance was very influential on a variety of artists (most notably feminist work). Schneemann created *Meat Joy* in 1964 as "a celebration of flesh as material" (<http://www.caroleeschneemann.com/meatjoy.html>, viewed December 27, 2012). The performance included raw fish, chicken, and sausages, among other materials, and centered on the movement of the performers' naked bodies in space and the improvised interactions among them and with the materials surrounding them. Schneemann's work explores ideas regarding sexual expression, the body, feminism, and traditional art practices and history. Her work is significant in relation to historical avant-garde work that was a distinctly white, male provenance, using women's bodies as a vehicle, but excluding them (as well as non-Western artists) from art making. Following Schneemann, several female artists employed food and cooking as a way to introduce women's voices into avant-garde art practice.

Martha Rosler's early work with video (like *Semiotics of the Kitchen*, 1974) and mail art (*A Budding Gourmet* and *Tijuana Maid* – both "novels" – were originally sent out in installments on postcards and included recipes in addition to text) continues the avant-garde's interest in new and undervalued forms, art in everyday life and materials, and strong ideological context. Rosler's early work had a strong feminist message and explored labor rights and socioeconomic hierarchies.

Karen Finley is another well-known artist who explores topics at the intersection of language, the body and female sexuality, and everyday life. She used food and food imagery in her work on numerous occasions, perhaps most notoriously by smearing her upper body with chocolate (standing in for excrement) in her piece *We Keep Our Victims Ready* (1988). Finley, who was influenced by artists like Schneemann, uses similar techniques of taking food out of its traditional context ("wearing" it rather than eating it), as one of the devices to deliver a strong political and ideological message. Like other artists mentioned here, Finley chose to perform her art in non-traditional and undervalued venues (nightclubs instead of art galleries) and used everyday materials in her work to emphasize her anti-art establishment attitude and to call into question traditional hierarchies in both the art world and the real world.

Food as material for art allows artists to follow in the footsteps of the avant-garde commenting both on earlier art movements and art institutions and on social-cultural practices. **Jana Sterbak's** *Vanitas: Flesh Dress for an Albino Anorectic* (1987), in which a model wears the 50 lbs dress made out of raw steak (which later was preserved and dried), comments on earlier feminist work (like Schneemann's) while also rethinking current social and cultural norms and practices, reflecting on both the meat industry and the fashion industry. **Janine Antoni** created her sculptures *Chocolate Gnaw* (1992) and *Lard Gnaw* (1992) by using her mouth as a carving tool. She displayed both the enormous, gnawed blocks and the leftover, chewed pieces she removed from them and shaped into lipsticks and chocolate hearts (Trippi 1998, pp. 142–144). In these pieces, Antoni

explores the idea of a traditional carved sculpture, replacing both the material and the tools, and comments on minimalist artwork, while also investigating the idea of consumption in modern society.

An example of an artist-driven restaurant, very different in feel from the Futurist Holy Palate, is **Gordon Matta-Clark's FOOD**, which opened in SoHo, New York in 1971. The restaurant was a group enterprise, designed to offer artists living in the area at the time an affordable place to eat, a place to work, and a space to display their art. It was in-line with Matta-Clark's other food-related work at the time, mostly concerned with experimenting with cooking tools and techniques like his *Fried Photographs* and *Incendiary Wafers* (1970–1971). The restaurant was created by Matta-Clark with Caroline Goodden, Tina Girouard, Suzanne Harris, and Rachel Lew with an original investment by Goodden. FOOD can be seen as a “political, economic and artistic project” evolving as a critic of the art world in the early 1970s (Morris 1999, p. 21). In addition to the regular, eclectic menu, the restaurant hosted special artist-cooked, themed dinners, like Matta-Clark's Bone Meal, which included “a variety of bone-based dishes” like aspic and oxtail soup. At the end of the meal, the bones were washed, drilled through, and strung as necklaces for the diners to wear (Morris 1999, p. 29). Several other projects were created at the restaurant or were inspired by it, like artist **Robert Kushner's** fashion show performance “Robert Kushner and Friends Eat Their Clothes” (1973). Kushner, who worked at Food at the time, acquired much of the raw materials for the “cloths” the performers wore through the restaurant. Goodden reflected that the restaurant, and much of the food work created there, was inspired by an atmosphere of new and experimental changes in the art world at the time and the search for new modes of expression, different types of spaces, and new materials (Morris 1999).

Rirkrit Tiravanija surprised visitors to a show's opening by serving a Thai curry instead of displaying artwork. He was concerned with institutional critique and his *Untitled (Free)* in 1992 was a way to use a new medium to take this critique

further and combine it with his unique set of interests. Tiravanija did not only subvert the gallery experience by serving a strong smelling, yellow curry instead of displaying art, he also did so in the entryway to the gallery, a kind of “nonspace.” Tiravanija explores the social interaction around the consumption of food. He says “. . . it's really not so much about coming to see things, but to be in it. [. . .] you're in it and the meaning is made through you. I think it's a different way of experiencing art in that sense. It's not art as life, it's different” (Trippi 1998, p. 156). Tiravanija locates himself as both continuing the work of earlier avant-garde artists, exploring the relationship between art and life, and questioning it. The experience, the interaction between the diners in the space using food as a frame, is the focal point of his work.

Mimi Oka and **Doug Fitch** chose the term Orphic to describe their artistic work. They refer to themselves as “sustenance artists, making works of art in edible media” (<http://orph.us> viewed 2012). Orphism was an avant-garde art movement that focused on abstract painting, highlighting the notion of painting for its own sake, not as a representation of anything else, and on the artist's ability to create a sensuous experience. Fitch and Oka perceived their work with food in the same terms, exploring food as a medium for its own sake and creating edible objects and later culinary events inspired to a degree by the Futurist Cookbook, like *A Night of Seating and Eating Color* (Tokyo, 1996), *Edible Still Life in Clay* (Tokyo, 1998 and NY, 1999), or *Ile Flottante* (France, 2000). In *Good Taste in Art* (1999 and 2000), the artists created handmade, colorful pasta that was then composed into framed pictures. The painting were displayed in a gallery where the audience could purchase them and then choose whether they would rather take their new acquisition home or take it next door, where chef Daniel Boulud would cook and sauce it for them to consume on the spot. In this project, Oka and Fitch involved their audience in the work directly, forcing them to make decisions that highlight their culpability in the process of consumption.

Composer **Fast Forward's** musical pieces using kitchen sounds are directly inspired by John Cage's work with found sound. Forward

created musical compositions from a variety of found sound, incorporating chance elements into his work. In recent years, he has devoted more attention to work centered on sounds derived from cooking and the kitchen environment, like *Feeding Frenzy* (1999 and on) and *Musique a-la-Mode* (2008, 2009), where the sound can be directly linked to the perceived action of the performers (Kirshenblatt-Gimblett 2007, p. 83).

Finally, to mention just one of a younger generation of artists, *Meat Poem #6* (Man Becoming Machine Chew to the Future) by Bradley Chriss (2010) can be seen as a direct descendent of the Futurists in both its interest in machines and technology and in its shock value: in this live performance and video work, Chriss stuffed raw, ground meat into his mouth, chewed it several times, and spit it into a sausage skin. The sound of his breathing and chewing was amplified to provide the score. Chriss's work highlights both the ongoing relevance of the Futurists work and the constant evolution and reexamination of the interaction between artists, audience, and food and consumption.

Avant-Garde Culinary Practice

Historically, culinary creations could not qualify as artistic creations since in order to qualify as Art required the creation have no utilitarian value and that it would have a lasting presence allowing its study and appreciation for years to come. Culinary creations would obviously be excluded from such a definition. However, modern art forced a change in what we perceive to be a work of art. From Dada's ready-mades to performance work, a new definition of art was required to encompass these new modes of expression.

John Dewey's theory of aesthetic experience asserts that an aesthetic experience is based on interaction and that ordinary experiences in everyday life could be appreciated as aesthetic experiences, insisting that traditional classifications of "art" hinder our appreciation and understanding of new forms (Dewey in Kuehn 2005). This is particularly relevant as we think of the experience-centered work of Fluxus and much of

the other work described above. It is also helpful as we think through the understanding of certain culinary creations as art.

Chef Ferran Adria's work has been publicly marked as art by his inclusion in the 2006 Documenta art fair in Germany. After considering several options of how to present his "art," Adria and his team decided that a true experience of elBulli art is dinner at elBulli. During the 100 days of Documenta, two visitors a day came and dined at elBulli. Rather than justify Adria's work as art (that has already been established by the fact of the invitation to participate), he would show "that cooking is cooking," that he is not a sculptor or a performer. Adria's Documenta team asserts that cooking is a unique medium governed by its own strict set of rules (Hamilton and Todoli 2009). Central among these rules is that the food needs to be delicious (a restriction that does not apply to artists working in this medium as many of the Futurist "formulas" demonstrate). Furthermore, cooking is multisensory and dishes must engage all five senses. It is also tied to a particular location and the dining experience is a total one, including all aspects of the restaurant. Finally, it is important to note that a restaurant is a business; unlike other artists, chefs need to run a sustainable business. Following these rules, this branch of the arts has its own avant-garde movement, one that tests the boundaries of traditional culinary practice and breaks new ground with experimental, innovative work.

Adria and his team examine the concept of avant-garde cuisine, defining it as a cuisine that is "most modern" at the time, "one which opens up new horizons," but find other concepts more useful to describe their work, like "technique-concept cuisine" in 2004: "a type of creative cuisine in which the chef aims not only to make a new recipe, but also to create a new concept or invent a new technique that will open up new horizons for his own style and for cooking in general" (Adria et al. 2005, pp. 176–177). In 2008, Adria preferred the label "techno-emotional cuisine" (Myhrvold 2011). Significantly, Adria and his team think through these terms and engage in an ongoing process to classify and frame their work, relying on tools from both the sciences and the

arts. Nathan Myhrvold makes a case for defining Adria's cooking as the first true Modernist Cuisine, claiming the key to the Modernist project in the arts is in the dialog between artist and audience, a dialog that Adria creates with the diner at elBulli. Myhrvold demonstrates that among Adria's goals are the impact of questions like "did the food make people think?" Did it engage them emotionally? (Myhrvold 2011, pp. 17–18).

Carolyn Korsmeyer argues that the most significant element in appreciating food as an aesthetic category lays in its "meaning-bearing qualities that give food its cognitive significance," positioning the subjective pleasure we derive from food as secondary (Korsmeyer 2008). A significant element in the work of Adria, as well as several other new or Modernist chefs, is that they are conscious of these "meaning-bearing" properties and employ them deliberately in their creations to give the diner pause and make her think.

Heston Blumenthal writes in *The Fat Duck Cookbook* "...a multi-sensory approach to food [, i]f it's done sensitively, it's not about turning the restaurant into a lab and the diners into guinea pigs. It's about creating a framework and canvas upon which each person paints their own images, memories and emotions" (Blumenthal 2008, p. 212). Adria in particular has systematically examined, documented, and analyzed his work over the years at elBulli. In a reflection on deconstruction he says: "This deconstructed dish will keep its essence and will still be linked to a culinary tradition, but its appearance will be radically different from the original. For this game to be successful, it is essential that the diner has a gastronomic memory, since the absence of references turns the concept of deconstruction into new 'construction' based on nothing" (Adria et al. in Myhrvold 2011). In this, Adria is like the artists described above; his work has meaning in the context of previous work in the field. He reacts against it or pays homage to it, but in order to fully understand his creation, the diner must have a prior knowledge and "read" the work as part of a historical development.

Chefs like Heston Blumenthal and Grant Achatz, among others, share with Adria not only the sophisticated methods of preparation and necessary technology – these are but the tools they

employ in creating their dishes – but also a way of thinking about their dishes conceptually. They are not only looking for new and pleasing flavor combinations and textures but also for ways to provoke an emotional and/or intellectual response in the diner, as seen in a poster on the kitchen wall at Achatz's Alinea: "capture spring. What is it? New, Fresh, Ice. Sprouts, delicate, gradual" (Max 2008). Other examples include Adria's *Thaw* (2004) reflecting on a natural phenomenon, Blumenthal's *Sound of the Sea* (2007), presented with a small listening device inside a shell with a specially recorded soundtrack, and Achatz's *Tomato* (2008), which makes the diner pause and rethink that particular product.

Most significantly, these chefs are constantly trying to innovate and surprise their diners. Much like the artists discussed above, Modernist chefs control and shape the total dining experience, engage all the senses, and create work that surprises and even shocks. They react against previous traditions and strive to make the diner pause and think and to reexamine things they may have taken for granted or disregarded.

Summary

The changes in the food world in recent years have made an impact on the way artists employ food in their work today. As the chef becomes more like an artist and the restaurant becomes a site for unexpected surprises and multisensory experiences, artists turn to food with new insights and interests. Since one of the hallmarks of the avant-garde is the strong presence of an ideological agenda, it seems a relevant question to end within the context of this entry. Like many avant-garde artists, it seems the strongest ideology common to these chefs is the search for innovation, the suspicion and reexamination of all previous rules and traditions, and the openness to inspiration from a variety of cultural and disciplinary sources. This ideology has powerful implications beyond the restaurant or the gallery. The growing importance of non-Western cultures and traditions and the questioning of habitual hierarchies and institutions, particularly when experienced

experientially – literally ingested, can be a very effective tool for change. It remains to be seen if the kitchen will follow in the steps of the art world to include more diverse voices beyond those of white men, as part of its deconstruction of tradition.

Food and the Moral Status of Animals

Introduction: Why Diverse Views on the Moral Status of Animals Have Ethical Significance

The fact that people have a range of personal attitudes toward eating is a social fact of little theoretical interest in itself. However, the fact that this diversity of attitudes toward food is often backed up by diverse ethical attitudes is of great theoretical import. This entry focuses on ethical attitudes toward animals as possible food. (Henceforth, by “animals” I refer to nonhuman sentient animals.)

People’s moral attitudes toward food, and in particular animals as food, are usually summarized in a tripartite way: omnivorism, vegetarianism, and veganism. This division is sensible because it tells us the practical outcome of the basic moral commitment: whether a person eats anything, or they eat only animal products but not animals, or they eat neither animals nor animal products. It bears specifying that this tripartite division is currently complicated by pescetarians, and by people who have more fine-tuned commitments that concern how the food is produced (e.g., in natural and respectful ways, or more or less environmentally sustainable). Of course, all of this matters from an ethical point of view. However, for the sake of simplicity, even if we consider only the basic tripartite division, it is not sufficient to focus only on the outcome of the attitudes. Indeed, beyond *how* people practically behave regarding animals as possible sources of food, it

also matters *why* people have such attitudes. The grounds of these attitudes are implicit or explicit ethical views that provide a set of reasons for having such attitudes. Some people adopt a certain attitude toward food because they rationally subscribe to a certain philosophical and ethical view, while other people have unexamined commitments, be they vegetarian or omnivorous. However, such unexamined commitments may unconsciously stem from more elaborated views. Hence, analyzing these views is fundamental from both a theoretical and a social perspective. Showing and clarifying the value sources of societal commitments regarding food may allow us to better understand *why* people have such commitments, and *whether they are rationally defensible*. On the basis of these considerations, the commitments may be discussed, rationally reconstructed or challenged, and possibly revised. As such, taking into account the diversity of views on the moral status of animals does not mean accepting all of them as legitimate.

This entry will be concerned with the ethical underpinning of the predominant attitudes toward food, in particular with respect to the treatment of animals, which is by far the most ethically contentious issue in relation to food. The section “[Five Main Families of Views on the Moral Status of Animals](#)” will outline the main positions on the moral status of animals and explain why these views form a continuum that is representative of other societal and religious views. The section “[Attitudes Toward Food and the Moral Status of Animals](#)” will clarify in detail what kinds of attitudes towards food the diverse views may endorse.

Five Main Families of Views on the Moral Status of Animals

The categories below will provide an outline of the main set of value commitments and beliefs regarding animals. Indeed, the following categories can be intertwined with other ideologically or sociologically relevant categories that contribute to making people’s views toward animals more complex and profound. The categories cannot

account for the whole complexity of people’s views on animals, although they certainly make sense of the most important dimensions.

The categories are arranged from those that place the greatest value to the status of animals to those that prioritize humans. In the first view (Animal subjectivism), animals are attributed autonomous (and equal) moral status as separate individuals. The second view (Pathocentrism) holds that we have direct duties toward animals in virtue of their interests, but individuals are not recognized as having any irreducible worth as such. The third view (Relationalism) rejects the jargon of rights and intrinsic worth independent of one’s relation with animals. The fourth view (Environmentalism) values collective entities (species and ecosystems), not (only) individuals. The fifth view (Humanism) holds that human interests usually have priority over animal interests despite animals having some moral relevance.

1. *Animal subjectivism*. This view is grounded on the value of subjectivity as an irreducible moral fact. Indeed, it holds that animals have a fully autonomous moral status insofar as they are individuals having subjectivity like humans. Of course, they might display a lower level of rationality or other properties that determine subjectivity. But most animals with which we have relations (at least mammals and birds) have mental capacities that make them distinct from one another, not replaceable and therefore worthy of direct moral consideration. The most famous formulation of this position is expressed by Thomas Regan’s idea of sentient animals as subject-of-a-life, which bestows on animals a form of status that carries with it inherent value and is analogous to the moral personhood of human beings (Regan 1983). Animals’ inherent value is generated by their having a fundamental property, the capacity to have experiences, which makes them worthy of direct and autonomous moral concern. In general, this entails a deontological theory of animal rights, according to which killing animals is morally wrong, except in those very rare cases in which the life of a person is endangered by an animal or we have to sacrifice an animal instead of a person. Such a perspective may require the full liberation of animals from human domination

(Francione 2008), or one might deny that this is possible insofar as autonomy is not an animal interest (Cochrane 2012).

2. *Pathocentrism*. On this view, what matters are conscious experiences, whether positive (typically pleasure) or negative (typically pain). Indeed, many animals, like humans, are sentient beings. Therefore, positive and negative experiences should be included in our overall consideration, just as we might include all positive and negative human experiences. The most prominent expression of this view is utilitarianism. Despite its seeming clarity and simplicity, utilitarianism provides different responses to the status of animals. Classical utilitarianism (e.g., Bentham and J.S. Mill) consider animals only as recipients of pleasure and pain, and accordingly hold that humans may raise them and justifiably take their life provided that such life includes more positive experiences than negative ones, and that their death is painless. In contrast, Singer's preference utilitarianism distinguishes conscious animals from self-conscious animals (Singer 1993). The former are limited to the experience of suffering and enjoyment, while the latter also have a sense of the future and more complex preferences. Hence, only merely conscious animals may be (painlessly) killed and replaced from a utilitarian point of view, while self-conscious animals cannot be replaced (Zuolo 2016).

Although this distinction makes the utilitarian perspective more complicated, it does not change the fundamental idea that there is only a single measure of moral concern. Accordingly, the moral status is simply determined by (the level of) sentience. No specific consideration to individuality is recognized and hence no protection of individuality per se, beyond actual experiences, is given. From this, it follows that animal suffering should be minimized and well-being promoted, and all practices incompatible with animals' ethological needs (such as industrial farming) should be abolished. But whether and how this should be done is conditional upon its consequences.

3. *Relationalism*. Animals, *qua* entities that can respond to human stimuli in a meaningful sense, are kinds of beings with which human beings entertain diverse forms of relations. On

this view, the moral standing of animals is constituted by humans' relations of concern and caring: given that human beings care for animals' welfare, and they interact and sympathize with animals, they have a responsibility toward animals according to the type of relations they have with them. This view, depending on personal relations and rejecting the impartial perspective endorsed by the previous two views, is ambiguous on the issue of the killing of animals. Since most important Relationalists are feminists, consider how the following writers diverge on this matter. Nel Noddings proposes a full-blown theory of special relations of caring, in which the killing of animals is admitted if there is no special relation with them (Noddings 1984, 159). Josephine Donovan, instead, claims that care feminist theory would not allow even compassionate slaughter of animals because an empathic communication with animals would clearly recognize that "no animal would opt for the slaughterhouse" (Donovan 2006, 310). Relationalism rejects the supposed impartial point of view of Animal subjectivism and Pathocentrism, and adopts a contextualist point of view. Hence, its conclusions are usually dependent upon the consideration of specific cases and individual lives.

4. *Environmentalism*. Environmentalism focuses on the natural character of animals, particularly their worth *qua* members of species that form part of a natural habitat. On this view, what counts are the collective components of the biotic system, in particular species, not individuals per se (Callicott 1989). Accordingly, the moral imperative is to safeguard the natural ecological equilibrium. Therefore, coherent environmentalism does not prohibit per se the rearing and killing of animals, but only to the extent that it is detrimental to the maintenance of ecosystems.

5. *Humanism*. Humanists hold that full moral consideration should be bestowed only to human persons. Morality is a matter of acting morally, and hence its subjects are moral agents. However, Humanists do not consider animals to be morally irrelevant, as if they were mere things. Rather, animals are said to have an inferior moral status in virtue of their not being moral agents, and thereby being incapable of following moral

rules, and by dint of their lack of other moral and intellectual virtues. Hence, on this view, human interests usually outweigh animal interests. But animals are owed certain direct duties of humanity and benevolence requiring, in particular, that their suffering be taken into account.

There are many forms of humanism, but the most important difference is that between inclusive Humanism and noninclusive Humanism. The former holds that only persons – thus excluding not only animals but also human marginal cases such as heavily mentally impaired people – are included in the realm of justice (Rawls 1971), which consists of reciprocal duties and equal rights. However, we owe moral duties toward animals as a matter of benevolence, in particular regarding their welfare. By contrast, noninclusive Humanists hold that animals are not owed direct moral duties, although they may be the beneficiaries of human moral actions. Indeed, noninclusive Humanists think that how we act toward animals is morally relevant, even though animals do not have an autonomous moral status. Noninclusive Humanists may have an indirect approach if the duty not to inflict unnecessary suffering is grounded on the respect of moral law and cruelty to animals may foster cruelty to humans (Kant 1997). Or they may take a traditionalist approach if the traditional uses of animals (including for sport and hunting) are part of a set of roles that foster human virtues and are compatible with animals' natural features (Scruton 2000).

These five views express the most abstract and general manner of grounding one's position toward the moral status of animals. But this abstract appearance does not entail detachment from reality, insofar as many socially held positions are reflected in these views. The next paragraph will discuss the specific position of these views regarding people's attitudes toward animals as possible forms of food. Here, just a few relevant examples will be presented in order to show the social relevance of these categories.

First, people committed to the abolition of animal exploitation and suffering – be they activists or private supporters – are clearly represented by Animal subjectivism or Pathocentrism. Second, those who are mostly concerned with

animals in the wild and with the survival of endangered species are clearly represented by Environmentalism. Third, the type of legislative protection that some Western countries have been granting to animals derive from reasons that appear in diverse views: in some cases, it is a matter of humane treatment (Humanism), sometimes what matters is sentience (Pathocentrism), while other times the protection has been granted to animals *qua* members of nature (Environmentalism).

Fourth, traditional majority attitudes toward animals have mostly been characterized by Humanism, insofar as the majority of people have considered animals to be inferior forms of life that, despite not being morally irrelevant, can be used for human purposes. Of course, some animals have been spared from this attitude, in particular companion animals. Such a disparity of treatment may be accounted for by Relationalism.

These views, finally, may also represent religious positions in respect of animals, which directly or indirectly inform the attitudes of many people. Other entries deal with these complex issues. It will suffice here to mention just a few relevant examples. To make a long story short by focusing only on the main Western religions, all monotheistic religions (Christianity, Islam, and Judaism) consider animals to be part of creation, and hence morally relevant. Despite animals not having immortal souls, human beings should be responsible for them (Waldau, Patton 2006). Humans have some duties toward animals in virtue of their common condition as creatures. Such duties are duties of humanity, kindness, and respect for animal suffering. These principles may be explained in terms of Humanism – because they are moral duties towards inferior beings – and Relationalism – because such duties at least in part arise in virtue of humans' greater capacities and responsibilities.

In sum, these categories cover a large, although probably incomplete, spectrum of societal positions. As said, people's concrete attitudes toward animals are often a patchwork of diverse views, sometimes resulting in inconsistent positions (Herzog 2011). However, at the abstract level,

we should be content with the fact that the five views outlined above cover an almost complete logical space of different possibilities from the most supportive of animals to the least.

One category that has been left out but deserves to be mentioned if only because of its important historical importance are those accounts that deny that animals can have feelings, or that they can experience pleasure and pain, and which argue instead that animals behave in a purely mechanistic manner. This view has been famously attributed to Descartes. But this denialism can be discarded because it rests on a conception of animals as mere machines, things, or entities without experiences – a view that has been proven false by science, and in particular by evolutionism and contemporary biology that have shown the many similarities between human beings and animals. While such a position might be of some historical or sociological interest, it is now hardly defensible at a theoretical level.

Attitudes Toward Food and the Moral Status of Animals

Having set out the main views above and having shown how they are not only philosophical doctrines since they can also represent other societal and religious positions, it is worth clarifying the importance of this analysis with regard to the issue of food. First, let us define the main attitudes toward food as far as animals are concerned.

Veganism is the refusal to eat any animals and animal products (including eggs, milk, and dairy products). Vegetarianism refuses meat but not animal products. Omnivorism considers all products permissible. Conscientious omnivorism (Cuneo 2016) accepts meat and animal products only if produced in a humane way, namely if the highest animal welfare standards are upheld in the rearing and slaughtering of the animal.

Animal subjectivism usually endorses veganism because animals have a right to life that cannot be violated for the sake of such human purposes as the gustatory pleasure of eating meat. Vegetables can provide the necessary dietary intake of proteins. The majority of supporters

of this view also endorse principled veganism, thus excluding the consumption of animal products (milk, dairy products) insofar as they necessarily involve human exploitation and animals have a right to a free life. However, not all Animal subjectivists maintain a principled veganism, because if we recognize that animals do not have an interest in freedom, some form of nonexploitative and nonkilling farms may be admissible for the production of milk and eggs (Cochrane 2012, 86–89). On the basis of this thought, one may hold a form of precautionary veganism. If animal products were produced in a nonexploitative manner, they would be permissible, thus admitting vegetarianism. But such forms of production are almost impossible to find in practice. As such, veganism is in practice the most defensible rule.

Pathocentrism may endorse a rather widespread but unprincipled and conditional veganism. Indeed, Pathocentrists may find the consumption of animal products more morally acceptable than Animal subjectivists. Moreover, depending on whether or not we consider animals as replaceable, their life may be taken. Hence, depending on the consideration of the type of life of animals at stake (whether they are deemed self-conscious or merely conscious animals), and depending on the overall calculation of welfare, contemporary Pathocentrism oscillates between veganism and vegetarianism. Old utilitarians, instead, would find meat-eating acceptable provided that it is produced in a humane way (conscientious omnivorism).

A similar oscillation may be found in Relationalism. If a majority of theories tend toward veganism/vegetarianism, some form of humane omnivorism may be justified in relational terms if we think that, depending on the type of relation we have, animals are (not) owed respect for their life.

Environmentalism may endorse some conditional form of vegetarianism or compassionate omnivorism. However, it would hardly justify any unconditional position, as what counts is the impact of food production on the environment, both in terms of its footprint and its impact on wildlife. Hence, Environmentalism may more easily accept omnivorism if meat is produced

in a traditional and nonindustrialized manner. It can recommend, though, a harsh reduction in the consumption of meat, short of a ban, in virtue of the impact that meat production has on natural resources.

Humanism may more easily license omnivorism than the other views. However, it certainly has internal resources for recommending conscientious omnivorism and for condemning industrial farming.

These attitudes can be, of course, quite mixed and/or conditional. As seen, with the exception of unconditional veganism, all these attitudes may be formulated in prudential terms or may be dependent on context.

At this point, one may ask whether these considerations cover all the possibilities at stake. Is there anything being left out? Should we have considered such attitudes as principled carnivorism, or a lack of commitment to these issues? Carnivorism is the position that holds that it is not only permissible but also commendable to eat meat for some good reason. Carnivorism, in its turn, can be divided into unreflective carnivorism and principled carnivorism. The former consists in a lack of moral awareness with regard to the eating of meat, and as such it cannot constitute a moral perspective. The latter, by contrast, holds that eating meat is not only permissible but also morally commendable. While such a view could be a moral perspective, it is not clear how it could be so. (Conscientious) omnivorism admits the eating of meat as morally permissible but does not consider it morally required, independently of how meat is produced. Carnivorism, instead, places more weight on the human interest in meat-eating; however, it is produced.

Can principled carnivorism be justified? Are there grounds in support of it independently of human pleasure? We have already discussed the idea that human interests usually outweigh animal interests (Humanism) and the idea that (some) animals can be replaceable (Pathocentrism). Hence, we are left with pleasure as an independent reason. Is the gustatory pleasure experienced in eating meat sufficient to justify carnivorism? Many doubt this because gustatory pleasure, if

not negligible, is neither a sufficiently strong reason nor a clear moral reason. Carnivorism may be grounded on intrinsic reasons, holding that eating meat is a good in itself and/or part of living a good life, and as such it is morally non-problematic; however, the meat is produced. Or it can be grounded on a lack of concern for animals insofar as they are viewed as lacking any moral considerability. Both these views are probably quite widespread at the societal level. However, it is difficult to see how they can be theoretically grounded insofar as, first, it seems quite implausible to hold that the ideal of a good life should include eating meat from animals reared and slaughtered in whatever way, and, second, the idea that animals do not have interests and moral considerability can be only grounded on a (false) conception of animals as mere machines. Modern science has already proven the falsity of such a view. Despite the social diffusion of these views, they are hardly defensible.

Conclusion

Diverse ethical views impact on our perception of what can be seen as “food” or how food can be legitimately produced. People may have different reasons for acting in a certain way (e.g., vegetarianism on the basis that killing animals is wrong vs. vegetarianism on the basis that it is environmentally burdensome). By looking at the reasons for the practical attitudes, rather than the attitudes alone, we can better understand people’s ethical choices, discuss them, and sometimes challenge them.

Introduction

As the need increases for sustainable methods of feeding the growing world population, questions have emerged about the quality and safety of foods currently being produced in affluent, developed nations. Various studies indicate that with increasing affluence, consumers tend to shift their focus from food accessibility to food safety, quality, and ethical and social dimensions that are of importance to them (FAO 2009; Viaene and Gellynck 1997; Bottonaki et al. 2006). Consumers with continuous access to food expect the products they purchase to be safe, nutritious, inexpensive, and high in quality and consistency (Beekman 2008), and substantial portions can afford to scrutinize the methods by which food is produced.

A number of reasons beyond relative affluence underlie such changes in consumer interest. Aside from the increasingly global nature of food production and trade and decreases in consumers' sense of connection to their food and their understanding of how it is produced, food safety scares, while relatively infrequent, are still a major source of concern. For example, high numbers of people still become ill from foodborne pathogens such as *Salmonella*, *Campylobacter*, and *E. coli* O 157 (Rocourt et al. 2003), and food recalls due to safety and quality issues are regularly reported. In addition to occasional food safety scares, recent UK discoveries of beef products tainted with horsemeat and animal abuse scandals occurring in the USA and abroad have raised concerns about the quality of care and treatment of agricultural animals used for food production routinely received. Further, conflicting information on the human health implications of the use of antibiotics and other technologies used in food animal production (Rollin 1995; Thompson 2008) as well as various reports of resource depletion and other negative environmental impacts of food animal production have helped to undermine consumer trust in the safety and quality of foods of animal origin (Ilea 2009; Wright and Middendorf 2008; Scruton 2004). The basis, therefore, for demands for food quality assurance is multifactorial and reflects both ethical and scientific concerns about modern food animal production and its societal impacts.

Ethical Dimensions of Food Quality

Food “quality” can be somewhat difficult to characterize as it refers to subjective as well as objective characteristics upon which consumers have varying ideas and priorities. Positive perceptions of food quality generally pertain to those features consumers find desirable. As such, food safety is inextricably linked to quality, since presumably consumers find safety in foods to be a desirable attribute. However, beliefs about food quality are increasingly tied to “credence attributes” or qualities of a product that are invisible to the consumer both before and after the purchase (Grunert 2005) such as the standard of care provided to animals used for food or the sustainability of the production method used. Because qualities such as these cannot be verified at the point of purchase (and it is often difficult to do so afterward), the capacity to meet and verify public expectations in these dimensions becomes a challenge.

Nonetheless, the ethical dimensions of food quality assurance (e.g., distributive justice concern such as the ways in which animals and people are treated, fair trade, or the broader environmental impacts of food production) appear to be of particular interest currently to consumers in western developed nations and elsewhere. Over the past decade, shifts in public interest toward “ethically responsible” food and “food activism” have become evident. Such interests are reflected in the growth of locavores, animal protectionists, environmentalists, and members of the human health community opposed to conventional, industrialized animal agriculture, which has become the predominant model of animal production in developed western nations. Singer and Mason (2006) describe this movement as “ethical consumerism,” wherein people actively seek out food production systems that align with their values. This type of consumer behavior is focused on procuring foods that do minimal harm to society and to the environment. Consumers with such interests tend to favor extensive production systems and are more inclined to seek labels with implied credence attributes such as “traditional,” “organic,” and “natural,”

(Harper and Makatouni 2002) because they believe them to be of higher quality and safety and perhaps perceive them to be more socially responsible (Croney et al. 2012). Studies indicate, for instance, that some consumers may associate organic production with positive attributes such as “chemical-free,” “healthier and more nutritious,” “earth-friendly,” and “fresh” (Raab and Grobe 2005). Consumers may also use animal welfare as an indicator of food quality and safety and in fact have been reported to buy organic food for these reasons (Harper and Makatouni 2002).

Clearly, the desire to seek out products with credence attribute labels is indicative of interest in discerning conventionally produced foods from alternatives that are perceived to be superior both in terms of quality and social responsibility. In regard to the latter point, large-scale, intensive food animal production has become highly contentious in recent years. Recurrent issues of concern relative to intensive animal production range from the safety to healthfulness of foods produced using technologies such as genetically modified organisms (GMOs) and antibiotics, to implications for human health, animal well-being, and environmental integrity (Verdurme and Viaene 2003). Claims that foods, especially animal products derived from industrialized, intensive production may be unhealthful and of poorer quality than those produced by other means are ubiquitous. Much of the concern about the quality and safety of foods of animal origin relates to the industrialization and intensification of animal agriculture. In particular, large-scale confinement production is often viewed as problematic. Such systems facilitate optimization of certain production efficiencies and have resulted in an abundance of food made available at reasonably low costs, which permits most consumers to spend only a small percentage of their disposable incomes on food (Thompson 2013). However, intensification, which amounts to getting as much economic value possible, heightens concerns that animal care and well-being may be sacrificed for economic expediency. The “high

technology” typical of industrialization has facilitated mechanization and cost cutting in labor, housing, feeding, and processing advancements in farm animal production and has allowed the respective industries to confine large numbers of animals in highly capitalized facilities known as CAFOs or concentrated animal feed operations. These production systems are emblematic of large-scale swine and poultry facilities in many parts of the world, such as the USA.

CAFOs have been met with mixed reviews despite their success in meeting consumer demands for safe, consistent, and relatively inexpensive foods and although they offer some welfare benefits to animals, such as advancements in feed composition and delivery, and benefits derived from indoor housing, such as protection from predators, parasites, and inclement weather. A major concern raised by critics is that technological innovations have paved the way for animal producers to alter the environments in which agricultural animals are raised and housed and that this may result in impaired animal well-being (see also Fraser et al. 1997). For example, billions of commercially produced chickens and pigs are kept in vast numbers in environments which are more congenial to increased productivity rather than to their ethological or evolutionary histories (e.g., battery cages for laying hens and gestational crates for pregnant sows). Farmed animals maintained in husbandry situations described by Rollin (1995) as akin to putting “round pegs in to square holes” may lack the requisite adaptations to cope with their circumstances, thus jeopardizing their well-being. Given this, technologies such as antibiotics and vaccines are often employed to mitigate production diseases in contemporary large-scale production operations. However, such interventions do not address the behavioral impingements on the animals, necessitating further technological investment in housing and management strategies that more broadly support animal well-being in industrialized production.

Consequently, there appears to be growing concern not just about the types of technologies being utilized in food animal production but about the rearing conditions that necessitate their use in

the first place. Numerous studies have shown that consumers have a positive willingness to pay for various animal welfare attributes, including opportunities for the animals to exhibit normal behavior or exercise and to have comfortable bedding and access to the outdoors (Norwood and Lusk 2011).

In addition to concern about the humaneness of on-farm practices, other environmental justice issues associated with industrial food animal production have also been highlighted as needing serious attention. These include the plight of farm workers vis-a-vis their health and safety, just wages, and various forms of discrimination (Wright and Middendorf 2008; Thompson 2007). For example, undocumented immigrants who have little to no protections themselves are at risk of being exploited by being poorly paid, offered little or nothing in the way of worker training or health care, and having limited protection under the law due to their status. Given these circumstances, it is not inconceivable that they might have little incentive to be proactive about performing rigorous animal care duties since they themselves may not be well cared for.

Environmental justice concerns also include how animal agriculture impacts water, air, biodiversity, species interaction and integrity, and land use. The whereabouts of CAFOs near rural communities, for example, raise distributive justice issues when the potential harms to community members (e.g., in terms of assaults to their health and quality of life) can put them at a gross disadvantage (Donham et al. 2007) relative to others who may derive benefits from CAFOs (e.g., access to affordable animal products) without being so immediately and adversely impacted.

Not surprisingly, given these concerns, assurance of the socio-ethical quality attributes of foods of animal origin has become a high priority for many consumers. For a number, it is a matter of ethical urgency related to substantive ethical issues such as consumer autonomy and procedural ethics issues like governance and trust in the global “foodscape.” Consequently many companies, organizations, and nations have developed quality assurance schemes as much to assuage public concerns as to ensure food safety and

quality and lend potential marketing advantages to those utilizing them (Grunert 2002).

Quality Assurance in Regard to Animal Welfare

Various schemes have been designed to assure consumers of the safety and, thus indirectly, the quality of foods. As noted previously, although quality and safety often go hand in hand, quality is not an absolute characteristic and neither attributes (safety or quality) can be directly observed (Holleran et al. 1999). Given this, food quality assurance programs are generally aimed at guaranteeing that certain specifications or requirements have been met during production. One commonly accepted way of ensuring food safety is by the application of Hazard Analysis and Critical Control Points (HACCP) principles which have been designed and implemented to facilitate food safety. Noting HACCP application implies that the food will not cause harm as the principles help identify hazards, set control points and limits, establish monitoring procedures, and outline corrective measures (Wood et al. 1998). In theory, similar principles should be able to be applied to ensure other aspects of food quality of importance to consumers. Attributes that do not necessarily affect the safety or intrinsic qualities of the product, but which consumers might find of interest, include animal welfare or environmental preservation.

Why the Impetus to Incorporate the Well-Being of Agricultural Animals into Food Quality Assurance?

Protecting the well-being of agricultural animals is clearly becoming a global priority (Fraser 2008). The World Organization for Animal Health (OIE) guidelines are indicative of the increasing global level of concern for the welfare of farmed animals (<http://www.oie.int/animal-welfare/animal-welfare-key-themes/>) (OIE 2005). Treaties in Amsterdam and Lisbon (Article 13) (http://ec.europa.eu/food/animal/welfare/policy/index_en.htm) have clearly expressed protection and welfare provisions for “sentient” animals, and EU directives

that have implications for national and trade policies mark more clearly guidelines for international land and sea transport as well as for euthanasia and humane slaughter. Recent developments also include national strategies like Australian’s Animal Welfare Strategy, which outlines obligations to animals in our mixed communities. Countries like Canada and the USA have put forward documents that reinforce best practices (note AG Guide and NFACC Code of Practice http://www.agr.gc.ca/cb/index_e.php?s1=n&s2=2010&page=n100430c). A new animal welfare legislation in Scotland in 2012 that replaces the Welfare of Animals (Slaughter or Killing) Regulations of 1995 also reflects a growing desire for national standards and uniformity (<http://www.food.gov.uk/scotland/news-updates/news/2012/dec/animal-welfare-scot#.UTvgdqUQgUU>).

Animal welfare has an “evaluative-normative component” that is linked to the quality of life of the animals and from a production standpoint has correlates with other normative components such as food safety and quality, worker safety, and environmental quality (Fraser 1999). The conception of farm animal welfare is rooted in public concern for how animals are treated and raised in CAFOs (Harrison 1964) and today integrates the interests and concerns of different stakeholders, including producers, governments, NGOs, and animals.

Trade policies, national regulations, voluntary industry programs, citizen and consumer initiatives, advocacy group initiatives, and media coverage are different ways in which protection for (farm) animals’ welfare is gaining attention globally. Some recent prominent drivers for change behind concern for animal welfare include consumer awareness of on-farm practices and social acceptability of standard practices; animal abuse scandals; changing relationships and image of food animals (they no longer are “creatures outside of society”); the prominence of animal welfare science and cognitive ethology and revelations regarding the capacities, behavior, and needs of animals; citizen pushback due to relatively little legislative protection for farm animals in many countries and the lack of a national animal welfare code or standard in some; ballot

initiatives and legislative activities like California's Proposition Two; influence from the European Farm Animal Protection policies on global trade partners; and pressure by special interest groups for industries to develop welfare guidelines and standards (Mench 2003; Croney and Millman 2007).

To that end, food quality assurance systems that at least partly address animal welfare and other latent ethical attributes of food production can take various forms. Regardless as to the nature of the quality assurance program, there must be documentation of the practices and procedures used, and verification and certification of these must occur (Holleran et al. 1999). For these reasons, most quality assurance schemes typically include the following components: traceability, certification, and auditing.

Traceability refers to the ability to track a food product all the way back through the supply chain (e.g., from a supermarket back to the producer). Traceability not only facilitates increased transparency in the supply chain but also provides an essential tool in the ability to identify and recall products that pose food safety or other consumer risks. Traceability can also be used to enhance certification programs. Certification programs, which are typically voluntary, involve meeting the requirements of an established standard for the production of food so that this can be conveyed to potential customers and other interested parties. In cases where certification is required for a producer or other entity to have their animals or products purchased by a customer or specially labeled and marketed, participating in a certification program may be only somewhat voluntary as the producer has little choice in complying if they hope to retain market access. For certification to be meaningful and credible, however, it is necessary to verify that the production standards have been met. Verification may be achieved through auditing or assessment. Third party auditing, wherein an entity with no vested interest in the outcome does the assessment, is considered the "gold standard" in verification and thus, facilitating consumer trust.

Assurance programs vary in regard to their scope and source of origin. For example,

voluntary programs can include international quality assurance standards, such as ISO 9000, national farm-level programs, such as the USDA's National Organic Program, the UK's Farm Assured British Pigs, and private standards or certification programs developed and employed by major retail organizations, such as the National Council of Chain Restaurants (NCCR), the Food Marketing Institute (FMI), McDonald's, Burger King, Marks and Spencer, European Retail Good Agricultural Practices (EUREPGAP), and British Retail Consortium (Mench 2003; Mench et al. 2008; Trienekens and Zuurbier 2008). Recently, voluntary assurance standards that emphasize agricultural animal well-being have become a major source of contention as well as change for food animal production standards and thus will be the focus of the discussion. For a more comprehensive review of different types of quality assurance schemes in the UK and USA, refer to Bredahl et al. (2001) and Trienekens and Zuurbier (2008).

In the USA and other western developed nations, the impetus to address the animal welfare component of food animal product quality assurance has been market driven, involving niche marketing of "humanely raised" products (Mench 2003; Croney and Millman 2007). Thus, the last decade of food animal production has been marked by food processors and retailers establishing quality assurance via development of science-based guidelines/standards with an emphasis on animal care and welfare. Such standards usually include common areas related to meeting the animals' physical needs, and thus, basic for needs provision of food, water, shelter (including ventilation, lighting, and the thermal environment), and veterinary care will be outlined. Depending on the goals of the assurance scheme, for instance, for those attempting to better address animals' behavioral and psychological needs, attention may also be given to the type of housing that is permitted (e.g., the use of gestation stalls or battery cages), the amount of space allocated to animals whether they are kept singly or in groups, and whether or not enrichment is required. In addition, the quality of animal handling and some aspects of management may be specified,

including practices that are forbidden (e.g., tail docking, nontherapeutic use of antibiotics) or required (e.g., analgesia for painful practices, such as dehorning of cattle). Further, some programs will specify the types of euthanasia that are considered acceptable and who may perform them and how often animals must be monitored.

Such assurance programs serve dual purposes. First, they provide a means by which to document that a specific farm animal product indeed possesses the attributes of interest (e.g., higher animal care and welfare or environmental impact standards), which is particularly important when it is difficult or impossible for consumers themselves to verify that the respective conditions have been met. Second, when the on-farm management of animals is tied to other aspects of production, such as their transport and processing, a “Total Quality Assurance” program can potentially create greater assurance and coordination of the standards under which the animals have been reared. By doing so, consumers potentially have some reassurance that animals have been properly cared for from “farm to fork.” Likewise, when production is integrated as is the case for US pork production, linking existing quality assurance programs such as those related to on-farm management of pigs (Pork Quality Assurance) to the transport of the animals (Transport Quality Assurance) can create multiple integrated points of reassurance and verification for consumers. In other words, they may facilitate coordination of the supply chain in industries which involve different sectors that are not necessarily controlled by one entity (e.g., a retailer), but still potentially impact the credibility of the claims associated with a particular quality assurance scheme.

Ethical Considerations Relative to Ensuring Animal Well-Being in Food Quality Assurance Programs

Those involved in animal production may view quality assurance via any of the available strategies – certification, traceability, or specialty labeling as a means not just of garnering consumer trust in an era of skepticism and concern about modern production but as a way of gaining some type of market advantage. Of course, gaining an

advantage is contingent on consumer knowledge about and receptivity toward such programs (Botonaki et al. 2006). Further, creating challenges is the apparent incongruence between what consumers state they want and what they appear to support via their purchasing behavior (Olynk et al. 2010). These differences have been suggested to occur via a phenomenon wherein people act as citizens in articulating their preferences, but act differently as consumers at the point of purchase. It is still unclear though to what extent consumers, especially those in the USA, are motivated to purchase based on their awareness of product attributes such as better animal welfare practices on the farm. The economics literature, for example, suggests that the emphasis on the USA *consuming* public is misplaced. Concerns regarding animals really seem to be an outcome of voting rather than consumer choices as such. This data suggests that in the USA, the debate about food animal welfare seems to be occurring less at grocery stores and more in media forums and at ballot boxes (see Tonsor et al. 2010). Some studies have shown that animal welfare is a key consideration for the European Union consumers in the broader context of environmental responsibility in food production. As discussed previously, these consumers look for labels associated with animal products perceived to convey higher ethical standards and rely on locally produced foods or those marketed as organic or “free-range” (Nilsson et al. 2004). However, consumer willingness to pay for welfare improvements is uncertain due to limited research and is not uniform (Norwood and Lusk 2011), especially in the USA. Moreover, the actual link between ethical values such as protecting animal welfare and organic food production methods may be weak and require verification.

Further, voluntary proprietary quality assurance in such a manner can be challenging. For example, these programs rely on shared economic interests between suppliers and retailers and can be patchy. Also, although scientists are often instrumental in developing many of the retail schemes and standards (Mench et al. 2008), it is sometimes unclear if the scientific information

was critically balanced with insights from other stakeholders, including producers who are directly impacted. In some cases, it is unclear whether the standards are based on scientific justification. In others, political and economic factors may overwhelm scientific ones and conventional practices may prevail despite scientific consensus that might dictate otherwise. Arguably, in the case of animal welfare, an inherently philosophical area of public concern, science alone is not enough to inform our view on our ethical obligations toward animals. Science alone cannot show that certain technologies are in fact “bad” for animals’ welfare, since what is “bad” or “good” will be influenced by one’s value commitment about what makes a life go better or worse (Heleski and Anthony 2012). In the absence of universal standards, latent value systems will likely influence how standards are formed, interpreted, and employed (Mench et al. 2011).

Additionally, this sort of “market approach” has limited outreach since the initiative targets only a small percentage of the consuming public as a way to drive change in animal welfare. It may not be the approach for all countries, especially if local consumers are not well informed about animal welfare issues or do not have the means to pay more for “added-value” products. Moreover, companies based in developing nations may be at a disadvantage as they may not be able to meet all of the safety and quality assurance demands imposed by consumers in developed nations pushed by Western markets. They may lack the means to fully control and trace all aspects of production and distribution that are critical to meeting quality assurance goals while remaining globally competitive (Trienekens and Zuurbier 2008). Consequently, an issue that is likely to emerge as ethically problematic is the establishment by globally operated corporations of disparate standards (for animal care, workers, environmental impacts) for different parts of the world. While it is essential that such companies consider the cultural norms and logistical constraints of establishing universal standards for attributes such as animal welfare, having different standards operating simultaneously under one brand creates many challenges, including the

potential to reflect inconsistent levels of corporate social responsibility within the brand. Increasingly, corporate responsibility is viewed as more broadly encompassing than just business ethics; thus, there is a growing trend to hold corporations morally and socially accountable for their various impacts on communities, the environment, and even on human rights by diverse stakeholders (Maloni and Brown 2006). It is therefore likely that in the future, quality assurance programs may be scrutinized and potentially used as indicators of global corporate social responsibility.

Summary

Quality assurance in food animal production has become a necessity, and the factors that influence perceptions of “quality” are rapidly expanding. Ensuring animal welfare is an increasingly essential component of sustainable, socially responsible production for those operating in developed nations and will presumably become so for those that are still developing.

In regard to animal welfare, quality assurance programs involving standards aimed at addressing animal care and well-being will need to address questions related to what is a good quality of life or baseline standard for morally acceptable animal welfare. Even voluntary standards programs should have teeth and be non-ambiguous and scientifically informed by advisory groups that are represented by independent experts (scientific and nonscientific, e.g., ethicists and economists), animal advocacy groups, members of the industry, and the public. They should be validated, balanced (i.e., consider the impacts on animals, environment, and people), consistent, effective for addressing animal welfare concerns, practical for producers and animal caretakers to adopt and execute, and sustainable (Croney et al. 2012). Public trust in and social acceptability of these standards is important, and thus, the viability of these programs should not be a function of the viability of the sponsoring body nor merely tied to their philosophy or funding at the time.

Perceptions of agricultural animal food quality involve consideration about which animal

production systems are supported in our local and global communities and have inherent social, ethical, and environmental justice implications. A central ethical challenge will be to promote equitable distribution of benefits and burdens for all those impacted by the animal agricultural policies and production systems that are adopted. Consequently, future development and refinement of food quality assurance programs may facilitate deliberation about (1) the nature and impact of vertical integration of different production systems, like swine and poultry; (2) the scale and effects of different farm sized on the behavior (including social) of animals, on local communities, workers' health and safety, public health, efficient use of land and water, energy policy, and food security; and (3) the relationship between science, ethics, and values in promoting and ensuring humane standards for animal agriculture.

Communication through food; Food art; Food medium

Introduction

The great performance artist Linda Montano once proclaimed, “Food is in the middle of everything” (2001, p. 181). In the opening montage to the Japanese edition of the pioneering cooking competition show *Iron Chef*, a judge exclaims, “I feel as if Iron Chef is speaking to me through the food!” These dual connotations of media – as middleliness and as means of communication – aptly synthesize the complex and multifaceted ways in which food functions to mediate human experience.

At its broadest, food serves to broker the sensory, social, and creative layers of human experience. Such mediations occur at various points of the food cycle – from production to preparation to consumption – shaping individual and collective identity.

At its root, the term media points to an intermediate state in time or space. Indeed, *media* is derived from the Latin root *medius*, which in the sixteenth century was roughly equivalent to “the

middle.” To this end, the term media can be situated in the aftermath of Hanson and Mitchell influential work on the field of Media Studies (2010), wherein they parse the various etymological and scholarly connotations of media and propose the following definition: “Media broker the giving of space and time within which concrete experience becomes possible” (Hanson and Mitchell 2010, xi).

Yet these authors also warn that the term media is sold short by definitions and is best employed as an interdisciplinary “critical concept” – or point of articulation – around which diverse areas of research might be newly apprehended, “. . . we are all, it seems, practitioners of media studies, whether we recognize it or not” (2010, vii-viii). In this way, they argue that media today, in fact, should serve as a holistic lens to the world in and of itself, functioning “in something the same way that the Freudian unconscious, Marxian modes of production or Derrida’s concept of writing have done in their respective domains” (2010, ix).

From this point of view, it is worth considering three critical perspectives of media and their relationship to our human interaction with food: first, food as storage and transmission medium; second, food as an extension of the human senses, and by proxy individual and collective identity; and third, food as an art medium with overlapping trajectories in the creative manipulation of food by humans.

Food, Storage, and Transmission

From the first critical perspective, we can infer that media connotes a capacity for storage and transmission. The notion of “storage and transmission media” has been most notably espoused by media theorist Friedrich Kittler to survey the emergence of optical and acoustic media technologies across human history. For instance, Kittler asserts that it is through the “storage and transmission” of the medium of writing that “culture was made possible in the first place” (Kittler 1999, p. 109).

Concurrently, the biological concept of the “growth medium” has long referred to the nutrient environment which offers cells or organs the

capacity to grow. While nutrients refer to the compounds foundational to human sustenance and growth, food, functionally speaking, can refer to the vessel through which these compounds are stored and transmitted. In the most elemental sense, then, food can be seen as the storage and transmission medium for the building blocks of biological life.

This delineation – as self-evident as it might sound – is useful in examining the human-food interactions at various point of the food cycle. Such material interventions occur not only on the physiological or ecological level but also relate to the economic, political, and religious spheres. Within each of these spheres, food functions at turns as both a one-to-one medium and a mass media.

From the nutritive point of view, food both stores nutrients (expands their temporal duration) and facilitates their transmission (extends their spatial reach). The peel of a banana, for instance, facilitates the storage of the delicate inner product containing absorbable carbohydrates, vitamins, and elements while its shape facilitates transmission. A banana is (most often) a one-to-one medium of nutritional storage and transmission. One can also point to foods which, like a hard drive, store and transmit nutritive compounds and, by proxy, caloric energy, on a mass scale. For example, the hunt and harvest of a single caribou or muskox in Canada’s Northwest Territories provide a community feast with a myriad of implications of preparation and consumption and their ultimate effects.

Conversely, on both individual and mass scales, food functions to store and/or transmit various elements of disease, from the direct transmission of harmful bacteria to toxic materials that adversely affect human health over time. It is partly due to food’s dual storage and transmission capacity – at turns beneficial and at times harmful – that it demures a near-endless site of ethical tension. Several ethical issues in food arise around the continual need to expand the duration of food’s temporal storage capacity while optimizing for nutrient transmission. In recent years, for example, much has been made of the promise of genetic engineering to increase the nutrient quantity and taste of tomatoes all while toughening the

skin to extend shelf life (Uluisik et al. 2016). Yet interventions into the nutritional storage and transmission capabilities of food can yield unintended results, such as the long-term health effects of certain chemical preservatives or the use of certain antibiotics in certain livestock (Krehl 1983; Ritz et al. 2012; Philips et al. 2004).

Remaining on the material plane, one can also point to food's storage and transmission features as an economic medium of exchange. At various points in human history, food has served as a formalized currency exchange between individuals, communities, and governments in highly structured economies. From at least 200 B.C., for example, wheat was used as currency in Egypt in a highly formalized central economy. Meanwhile, cacao beans were used as semiformal currency throughout the Mayan civilization, and since the Middle Ages, parmesan cheese has been accepted for financial transactions, including as collateral for bank loans.

Several historians have noted how, from the Middle Ages until the mid-eighteenth century, salt, sugar, and spices along trade routes served as key media of economic exchange and also the transmission of cultural values (Gilbert and Reynolds 2005).

Food reserves continue to act today as an increasingly critical *political* medium, storing and transmitting power dynamics between nations. Such diplomatic jockeying – with food stores as the pawn – often comes with far-reaching implications. The lead up to the 2008 food price spike, for example, was fueled by various nations alternately banning imports and exports and at times allowing food to rot in order to maintain political power (McMahon 2014). Throughout history, countless other examples exist of food being dumped, redistributed, or outright wasted in order to accelerate political outcomes, hinting at its use as a political medium above and beyond nutritional value. It is thus, perhaps, that the FAO classifies food security as one of the main factors in global peace in the upcoming century (FAO 2017).

Finally, food can be seen as vehicle of religious storage and transmission. Imbued with the function of bridging the material and spiritual realms, food can serve as a religious medium either as a

manifestation of the spiritual – to be materially incorporated by the human or as encoded material to be transformed into the spiritual path. Examples of the first include the Catholic Eucharist – a medium of the body of Christ to be incorporated by the practitioner – and the tasting of blessed meat and alcohol in certain Vajrayana Buddhist rituals, media for the spiritual properties of bliss and emptiness, respectively. Meanwhile, Kashrut, or Jewish dietary rules, provides an example of the second type of religious food medium, wherein specific food rules such as the abstention from pork or the separation of milk and meat provide a material means to moral virtue and, by proxy, proximity to God.

Food as Extension of the Human

To Marshall McLuhan, often cited as the accidental founder of the field of Media Studies, media came to signify not the middle but rather the periphery: “extensions – extensions of man, extensions of the central nervous system...” (McLuhan 1964, p. 3). Thus for McLuhan, air and skin were media as much as radio and film.

McLuhan wrote extensively, for example, on how “the wheel extends our feet, the phone extends our voice, television extends our eyes and ears ...” (McLuhan 1964). Just as these audio, visual, and haptic media extend the senses of sight, sound, and touch, so too do food practices extend the senses of sight, sound, and touch – with the notable addition of taste and smell. Not only is food thus a medium in the McLuhanesque sense, it is a particularly fitting one in that it has the ability to extend *all* five senses. McLuhan was a fierce advocate of the inseparability of the senses, a rather audacious and unpopular claim in his time that has nonetheless been proven increasingly true by neuroscience: “There is little possibility of answering such questions about the extensions of man without considering all of them together. Any extension, whether of skin, hand, or foot, affects the whole psychic and social complex” (1964, p. 6).

His oft-misunderstood statement, “the medium is the message,” is perhaps best clarified in his

notion of “scale.” For McLuhan, not only are media extensions of a person, in that they allow us to reach further than our actual spatial or temporal position, but “the personal and social consequences of any medium – that is, of any extension of ourselves – result from the new scale that is introduced into our affairs by each extension of ourselves” (1964, p. 23). In “operational fact,” then, to McLuhan, there is no “content” or “message” outside its environment. To McLuhan this scale could be omnipresent and subtle as air or light or formally explicit as television.

Such a notion of media has strong ramifications in the formation of one’s sense of place, individual identity, and shared culture. To both the cook (producer) and eater (consumer or “end user”), food introduces a new scale into the equation and functions to extend the senses – and sense of place – beyond the immediate present in a cyclical process.

The concept of terroir provides one such illustration. The product of long “layerings” of geographical and cultural forces, terroir, is a gastronomical product rooted economically in a distinct (often small) region and its people. One of the foremost scholars of terroir, Amy Trubek, demonstrates how terroir quite literally functions as a “taste of place,” extending the sensory and cultural experience of a local landscape beyond its immediate position in time and space (Trubek 2009).

The discernment of taste as sense of place is a process in a process that relies both on a local material reality and its discursive framing. This process has been studied by theorists who account, for example, for the social experience of wine tasting in the close relationship between discursive interpretation and taste experience (e.g., Vannini et al. 2010). Paying particular attention to the “social drama” of wine-tasting festivals, they propose the concept of “somatic joint acts,” whereby actors consuming substances within a particular mutual network in fact co-constitute a layered experience of taste that is highly dependent on the activation of mutual discursive fields (“somatic accounts” activated by “taste vocabularies”) (Vannini et al. 2010).

The cyclical nature of this process can be seen in the history of curry in the UK. Introduced to the

UK in various waves variously as “ethnic” or colonial “extension” to another place and its cuisine, the current concept of curry in the UK has widely hybridized with food practices of the dominant culture. From such a process, such “national treasures” as “chicken tikka masala” and “chips and curry” have been born and at turns labeled the UK’s national dish. The degree to which such foods are entrenched into a dominant food culture is, paradoxically, often expressed remotely, via extension, such as a plethora of curry restaurants at various Spanish seaside resort catering to British tourists. In a final twist to the curry case study, one should note that the dish known as “curry” itself was heavily influenced by Portuguese and British colonial endeavors in India, nationals of whom who had brought their own “ethnic food” practices with them as extensions (Basu 2003).

This shows the oftentimes self-referential effect of “gustatory media” (in this case a familiar dish), which can reveal a sense of place or identity via sensory extensions beyond the present environment. Indeed, a strong sense of national cuisine is often defined from afar.

McLuhan’s notion of media as sense-extensions accounted for such cycles of near/far or proximity. Indeed, to “extend” the senses or self afar necessarily infers an anesthetizing of input from a more proximal position. McLuhan colorfully referred to this “amputations,” noting that media “by which we amplify and extend ourselves constitute huge collective surgery carried out on the social body” (1964, p. 76).

The introduction of any media into our daily life alters sense ratios, often with paradoxical effects. “The effect of radio is visual,” McLuhan wrote, referring to the power of radio to stir up vivid imagination and political action among listeners in its earliest days (1964, p. 76). Indeed when viewed as a multisensory medium, the ethnic dish can allow us to sense elements of place or identity that might previously have been imperceptible. Indeed, the very intensity of ethnic food may lie in its “extensory” function, the idea that it reminds us of something else of *something else*.

This might go some ways toward explaining why countries known as utopias of so-called ethnic food such as the United States are at times

characterized as lacking clearly defined national cuisine (Long 2014, 2015; Gabaccia 1998).

Finally, one might point to semiotic models of taste which represent an attempt to bridge these concerns. Jean-Jacque Boutaud proposes a “Taste Image” which accounts for how gustatory meaning is generated by way of the C.S. Peirce’s semiotic model. Boutaud proposes three primary factors in a semiotic taste analysis: esthetic (sensory), pathetic (emotional), and cognitive (informational), arguing a privileged place for “social modes of perception” in that “the synesthetic experience of taste involves, over and above its sensory reception, the sum of the subject’s experience” (Boutaud 1999, p. 339). Boutaud “Taste Image,” as a semiotic model, is axiomatic in that it attempts to take into consideration a relationship between the above three factors (esthetic-pathetic-cognitive). Boutaud contends that such a Taste Image cannot be thought outside specificities of relations between bodies and general environment: “the reaction provoked will be context dependant, and that correspondingly one sense will be privileged at the expense of the other” (Boutaud 1999, p. 339).

Food as Art Media

Art media generally refer to the forms or materials employed by artists (Davies 2005). An art medium may therefore describe a particular type of art (e.g., ceramics) or a specific material used within a single work (e.g., plaster in a mixed media piece). The use of food as art medium falls into two principal categories: first, the creative use of food within a distinct professionalized domain, often referred to as the “culinary arts,” and, second, the use of food within traditional fine arts disciplines. Though historically these categories have had relatively thick borders, the two often intertwine in contemporary practice and function.

Though it contains parallels to other art media such as paint, food also provides unique capacities and challenges to the artist: on the one hand, it has the potential to perform creative work on all five senses (often at once); on the other, it has a natural proclivity to decay, a lack of “material persistence.”

The use of food as an art medium dates back at least to the Upper Paleolithic Era (13,000 BC) and its paintings. Vegetables were used in juice or powder form for pigment, while animal and other fats were used as binding media (Sandars 1995).

Since then, food has been used in both formal and informal ways within the purview of the traditional fine arts, including painting/drawing, mixed media, and performance art. One celebrated example from the Renaissance era is Giuseppe Arcimboldo’s human portraits composed of vegetables and fruits.

Long before the formalization or professionalization of the field of “culinary arts,” monarchical cooks in the Middle Ages courts – much like resident composers – created elaborate *entremets* (“between dishes”) in the form of edible buildings, landscapes, castles, etc. intended as much to dazzle and impress as to be consumed. The latter two functions still form a significant part of the concern of food as art today. Though culinary art did enjoy a certain slice of the same prestige of the patronage system which supported, for example, court painters and composers, it never gained the same tradition of public resource allotment, which led the “artistic” portion largely dependent on market forces. At its broadest, the domain of culinary art refers to a formalization of culinary craft and labor as of the nineteenth century in Europe. Grounded in the influential work of Escoffier and to some extent Careme and Dumas, this movement laid the foundation to elevate the value of creative culinary practices and systematize the profession. Due in part to this reality, the trajectory of the culinary arts largely professionalized stream well into the twenty-first century.

The notion of the chef as an artist – working in an expressive or communicative medium – gained renewed mainstream acceptance beyond its traditional confines beginning in the late 1990s off the back of an explosion of specialty television and consequent dawn of food TV. Yet this mainstreaming of culinary art occurred in tandem with a growing fixation on celebrity chefdom, complicating once again public notions of what in fact culinary art entailed and who was entitled to practice it (Rousseau 2013). The advent of the internet

further widened acceptance for the notion that lesser-known chefs as well as restaurateurs and food bloggers could be artists in the medium of food. This spread was aided by the plethora and abundance of audiovisual media serving to promote this notion by extending, artificially, the dish's trace in time and space. Yet once again, one might note a paradoxical counter-effect. Several researchers have pointed out that the rise in appreciation of culinary art has been coupled with an increasingly distant, distracted, audience and eating culture, a phenomenon that has at times led to tensions between eaters and chefs (Rousseau 2012).

Concurrently in today's contemporary art world, mixed media installations have come to commonly include food materials, often with a performative element. One demonstrative example is Kara Walker's 2600 sq. foot sphinx-like sculpture, covered with 80 tons of sugar installed in a historic sugar factory whose function is to critique race, labor, and colonialism in the United States (Walker 2014).

The above is an archetypal example of the use of food as a contemporary "fine art" medium. Such work comes in the aftermath of massive increase in the use of food in contemporary art since the rise of performance art, a key turning point for the ways in which food was used and conceived of in art. Early work deploying food as a performance medium included the Futurists' "Extremist Banquets" and "Tactile Dinner Parties" – participatory, "relational" performances comprising theatrical feasts of unconventional "dishes" combined with theater, music, and plastic arts (1921–1931) – setting a framework for their radical re-formation of the "culinary arts." Their notion of the inseparability of the five senses—and their imperative to engage them all—was ahead of its time.

Much work followed in the wake of this vision of food performance; several other performance artists sought to reframe gustatory products as art media, froze and amplified the performative gestures of the cooking process, and reasserted the authority of touch, taste, and smell within communicative acts.

A wave of performance art exploded as of the 1970s, often using performative elements of the

Futurists alongside conventions of the culinary arts with a feminist critique. Notable examples include Suzanne Lacy's "Dinner Performances" between 1979 and 1989 which include, among others, "River Meetings" (1981–2) and "International Dinner Party" (1979). In this series of events, Lacy furthers the Futurists' interests by reframing the dialectic between intimacy and publicity in communal gustatory events, with a particularly feminist lenses. Lacy's dinner party installations – sometimes formally prepared, other times relying on a potluck format – became regular features embedded into urban landscapes, and the artist welcomed a snowball chain letter invitation process, leaving each event semi-constrained yet highly unpredictable. Reframing these crucial yet uncelebrated "everyday" events in local women's lives as public events (they took place outside, in historic buildings, theaters, etc.) is what allowed Lacy's dinner parties to become "a performance." Lacy's work has been credited with "the possibility of creating new forms of commensality or resignifying what it means to eat together" (Kirshenblatt-Gimblett 1999, p. 17).

A host of notable performance pieces followed in this wake such as Ro Malone's "ReadyMade" bread book (1981), or Jana Sterbak's flesh installations (Vanitas 1987; Chair Apollinaire 1996), or Allison Knowles' participative salad-making concert.

The aftermath of food's prolific use as a performance medium has led to increasing interdisciplinarity in notions of art and performance and a blurring of the lines between chefs, artists, and every day cooks. Beyond simply regarding food as a static or inert medium of performance art, some scholars have argued for a two-way view of its mediatory capacity, wherein food is not simply *performed* but also *performative*, enacting person and identity. (Curtin and Heldke 1992; Kirshenblatt-Gimblett 1999; de Certeau et al. 1998).

Summary

Food functions in a mediatory capacity vis-a-vis human experience in three principles. First, it

serves as material for nutritional, economic, political, and religious storage and transmission. Second, it serves to extend the senses and sense of individual and collective identity through cooking and eating practices. Third, food is an art medium used in the domain of the culinary arts as well as the traditional fine and performing arts.

Introduction

Food assistance and food charity refer to practices where public, private, or third sector actors provide food (or resources to acquire food) to individuals or households that face hunger or food shortage. The food is provided for free or for a minimal cost and the provision is conducted through varying services like food banks. Domestic food assistance practices are realized in relations between a collective (the provider or donor) and individuals (the recipients of the assistance). For those international practices of food aid that take place between collectives, typically nations or global food aid organizations and recipient countries, see the entry for “► [Food Aid](#).”

Currently, approximately 800 million people in the world are undernourished and even more lack food security. According to FAO (2015), food security exists when “all people, at all times, have physical, social and economic access to sufficient, safe and nutritious food that meets their dietary needs and food preferences for an active and healthy life.” The practice of providing food or resources to acquire food to needy individuals or households is probably almost as old as the history of the civilization, yet its institutionalized forms are relatively new. Nowadays, the organized forms of food assistance are widespread. Numerous international, national, and regional

organizations participate in the food provision activities and there is a great variation in how, where, and by whom the food is provided for those in need.

In this entry, food assistance refers more specifically to the social and public policy measures exercised by the public sector, whereas food charity denotes those activities that are conducted by third sector organizations (including religious communities) or business enterprises. The main difference between the two is that the public sector may have obligations that are determined and regulated by eformal, usually democratically negotiated norms related to social security. In contrast, the third sector and business actors decide their practices and norms on their own (within the limits of allowed practices), and the third sector practices are based on voluntary participation. From the ethical viewpoint, the difference between the public and nonpublic actors is important.

Many of the ethical aspects regarding food assistance and food charity are closely related to the fundamental points of morality: the equal dignity of all human beings and the idea of universal human rights that includes the right to food due to its vitality for human life. This entry begins with a characterization of the relation between some general moral principles and the provision of food for hungry people. After that, the entry focuses in more details to the ethical considerations that regard food assistance (provided by the public sector) and food charity (provided by the third and private sector) in its different forms. For further ethical considerations on the latter, see the entry for “► [Ethics of Food Charity](#).”

Universal Needs and the Right to Food

Adequate nutrition is necessary for staying alive and living a worthy human life. The central principle that lies beyond the provision of food to needy people is the idea that all human beings have an equal right to live a dignified life, which necessitates freedom from hunger and undernourishment. This imperative forms one of the grounding principles for theorizing ethics and it is

endorsed in different approaches to morality and justice in the context of food and hunger. These approaches include, but are not limited to, utilitarian ideals that aim for the maximum aggregate of preference satisfaction (Singer 1971), the human rights approach (Pogge 2002; Ziegler et al. 2011), various theories of social justice (e.g., Pogge 2002; Nussbaum 2011), and Kantian theories that emphasize our obligations (O'Neill 1987). In whatever way the equality of humans is understood in detailed terms, the satisfaction of a biological basic need like adequate nutrition is an essential element of equality, because it is a precondition for the exercise of any other capacities and autonomy in one's life.

The equal dignity of humans and the right to food have been institutionalized in the Universal Declaration of Human Rights and the International Covenant on Economic, Social and Cultural Rights (for more details, see “► [Human Rights and Food](#)”). The right to food is, then, one of the globally agreed fundamental (non-negotiable) human rights. The right to food means “the right to have regular, permanent and unrestricted access, either directly or by means of financial purchases, to quantitatively and qualitatively adequate and sufficient food corresponding to the cultural traditions of the people to which the consumer belongs, and which ensures a physical and mental, individual and collective, fulfilling and dignified life free of fear” (Ziegler et al. 2011, 15). Although there are some differences in details, the core of this definition is essentially similar to food security. By definition, rights should also invoke corresponding obligations; the right-bearers are entitled to certain goods and can express related claims to the obliged parties. The right to food is interpreted to invoke the corresponding obligation to states to ensure that all citizens have the capacity to feed themselves in dignity. The obligation involves the duties to respect, protect, and to fulfill this right (Ziegler et al. 2011, 15–20).

In normal conditions, people are supposed to have capacity to feed themselves on their own or with the help of other family members. In those circumstances, the state obligations are mainly limited to respecting and protecting the right to

food; that is, the states must support and protect conditions where people can acquire means to purchase food or produce food on their own if they choose to do so. However, the ability of an individual to feed oneself or one's family may fail for various reasons, such as economic uncertainty, unemployment, or old age. In those cases, the right to food gives rise to the obligation to the state to provide those people with either food or other resources for acquiring food. Food assistance is the publicly governed measure used to ensure the food security of households or individuals who cannot secure it on their own. Sometimes larger groups of people face food insecurity simultaneously due to unexpected acute circumstances like natural disasters. This entry does not address such cases specifically because they are largely different from the cases discussed here and the same ethical considerations cannot be applied to both situations.

Public Food Assistance

Food assistance can be considered as an obligation of the state to ensure the fulfillment of universal human right to food (Ziegler et al. 2011). This obligation is based on the view of states as actors that can, and ought, to ensure the fulfillment of the rights of their citizens, as a counterpart to their rule-making authority over the same people. States have responded to this obligation in different ways (and, arguably, many states have not responded to it in any active way). The obligation to respect and protect the right to food means two things. First, the government should not impede the access to food or erode the availability of food by its own actions. Second, the government must pass and reinforce laws to prevent other actors (like powerful people or collectives) from violating any person's right to food. These two obligations are general duties to ensure that the rights are not violated; they do not require active measures in normal conditions. In contrast, food assistance relates to the obligation to fulfill the right to food and requires active measures that are targeted to those in particular need. In the poor and developing countries with a relatively high prevalence of

hunger and food insecurity, a common approach to the challenge of feeding people is international cooperation. Other countries or international organizations provide food and/or development aid and cooperate with the local actors in the recipient country to provide people with food or means to acquire it. The ethical questions that relate to the food provision for highly food insecure regions are discussed in the entry for “► [Food Aid](#).”

In the industrialized welfare states, the standard approach to food security and the right to food is to view it as a central element of the basic subsistence and social security. Food assistance is in those cases covered by the broader package of welfare state measures and subsistence security network, which usually involves financial support (for acquiring food and other necessities) rather than in-kind food assistance (assistance in the form of food itself). Food services for disabled and elderly people are a common exception for this, since in those cases, the access to food is restricted due to physical rather than economic factors. In some cases, food assistance can be provided in the form of vouchers or debit cards (granted by a social welfare officer) that are particularly targeted for purchasing food products and other daily necessities. They cannot be used for buying other things like alcohol or tobacco products, but the cardholder can usually exercise consumer sovereignty by making individual decisions about how and what kind of food she wishes to purchase with the provided support (some debit card systems may involve stricter consumption limits even regarding the food purchases, though).

The financial support is supposed to provide individuals with the resources needed to avoid food insecurity, given that the availability of food or physical access to food is not limited. The monetary forms of social security promote effectively positive freedom, the actual opportunity of a person to do different things and make choices between them. Positive freedom promotes the sense of consumer sovereignty and individual autonomy. A citizen who receives income support has, even if within the financial limits, a freedom to choose between different ways to acquire food and to realize at least some personal food preferences. In contrast, the direct provision of in-kind

assistance only ensures that the assisted individual does not suffer from malnutrition.

In political philosophy, the equality of citizens – a fundamental precondition for justice – is argued to require their equal autonomy (O’Neill 1987) or equal opportunities (Nussbaum 2011) for a dignified life, rather than equality merely in terms of biological need satisfaction. From this viewpoint, the public provision of food assistance through financial measures and as a part of broader social security framework promotes justice more efficiently and is hence superior to in-kind food assistance, even though both measures can be used to secure basic needs. The provision of food assistance in a financial form also goes in line with the fact that food insecurity is closely associated with the broader issue of economic inequality and poverty, and the two cannot be separated (Nagel 1977).

There are also other normative arguments about why publicly provided food assistance should be financial rather than in-kind. Although human needs for nutrition can be defined biologically, the notions of food security and the right to food emphasize the importance of an adequate regard for food preferences. Food is not only a source of nutrition but a socially and culturally important matter, and the possibility to follow one’s own ethical values and cultural traditions regarding food is important for the sense of self-respect and autonomy. In-kind food assistance does not usually leave much room for choice and, in the worst case, a person relying on such assistance has to “choose” between eating food that goes against one’s personal moral principles (on ethical or religious grounds) and staying undernourished.

Food Charity

Charitable food delivery, or food charity that is practiced by third sector and private actors, can be organized in different ways, and there are great regional variations in the practices. For example, in North America and in the UK, there are national umbrella organizations that coordinate operations, and the delivery sites may be established as franchise chains. There are plenty of private NGOs and

faith-based actors in the field. At the street level, the distribution takes multiple forms: giving handouts to beggars, breadlines, soup kitchens (see also ► [Emergency Food System: Soup Kitchens and Food Pantries](#)), food banks, or even community shops for poor people, where the idea is to offer low-income customers heavily discounted food. Essentially, charitable actors do not compete with enterprises that operate on the primary market. Rather, they distribute food to the needy for free or with a price below the production costs.

Moral philosopher Peter Singer (1971) argues in his famous article “*Famine, Affluence, and Morality*” that we are morally obliged to alleviate the suffering of other people (by, for example, giving to charity) when we can do so without comparable costs to ourselves. For anyone who does relatively well, it would simply be wrong not to help a hungry person, since food is such a basic need and helping in that regard would not require much or risk the helper’s personal food security. People who operate in the food charity organizations meet this kind of individual moral obligation through the charity action. However, despite the apparent individual obligation to help a hungry person, the overall practice of food charity as a way to meet such obligations involves many ethical issues that require further consideration. The major conundrums of food charity are next discussed, first with regard to the different ways of practicing food charity and then as a bigger question that relates to the whole idea of charitable food delivery.

One of the ethical concerns regarding various food charity practices is their relation to human dignity. Although charity acts are basically benevolent, their nature as gifts or alms from the well-off to the poor people stigmatizes the recipients, and some delivery practices may reinforce this impression. A stigmatizing division emerges where a group of people is viewed as relying on the noble-mindedness of the individuals who are well-off. The dignity of those who have to (literally) stand in a breadline to receive handouts is suspended, and the experience of having to wait in the line to receive basic necessities (of sometimes inferior quality) when others wander freely in abundant grocery stores can be a

humiliating experience in itself. Moreover, the practices of giving charity do sometimes involve humiliating elements such as unfriendly or condescending behavior (that indicates the moral superiority of those who give), denial of assistance, or discrimination by race or religion. Some organizations also require the recipients to make an account of their economic situation (to prevent the misuse of donations), which deprives the clients their economic privacy and signals mistrust. The stigmatizing effect often relates to the unspoken assumption that the need for food is caused by the person herself and signifies failure as the member of a society.

Another potential problem concerns the background of the charity providing organizations. At present, faith-based organizations and churches are active operators in the field of charitable food assistance. This is consistent with their moral principles that often emphasize the importance of charity practice. However, it also means that the recipients of food charity often have to expose themselves to religious activities (such as praying, services, or spiritual music) or religious symbols whether they want it or not. For the members of the same church, this is not problematic, but it may create the feelings of oppression or anxiety for those who belong to other religious groups. Charity recipients have made up different strategies to get through the religious contents attached to food provision (Salonen 2016).

Framing the food provision as a matter of charity is also misleading. Those who are asked to give charity still have the freedom to decide when the given help is sufficient (or whether one wishes to give it at all). In general moral terms, it is praiseworthy to give charity but not morally wrong to *not* give it. The acts of charity enjoy the quality of voluntariness that moral obligations do not: if we have an obligation to do something, it is wrong to not do it. Moreover, charity does not question the legitimacy of the status of charity givers as the well-off who *can* give for those who *do not have enough*, or the legitimacy of the system that creates and maintains such inequalities. In other words, the framing of charity does not question the legitimacy of the present situation characteristic of great inequalities (Nagel 1977; Pogge 2002).

Food charity is often insufficient for meeting the right to food or food security, because it satisfies the need for energy intake but less often the conditions of adequacy and acceptability of the food. The problem is similar to the one regarding the provision of in-kind food assistance: charity entails the deprivation of opportunities to make choices. Yet, the problem is in one sense greater with charity, since charity does not involve an idea of *rights*: there is no possibility to *claim* for something one would be entitled to have. People who rely on food charity rely on whatever is available in the food banks, soup kitchens, or breadlines. Selections of available foodstuff are often unexpected and occasional. Even their nutritional value is sometimes highly questionable (Poppendieck 1998) due to their origins. In addition, charitable food assistance is not accessible for all people in need, yet no one can claim it should be. For example, in rural areas, the distribution of food is often limited, and on the other hand, physically disabled or elderly people may have poor accessibility to food assistance even in urban areas.

Charitable food assistance may be the solution to the acute problem of hunger but does not address the root causes of poverty and food insecurity. The most common reason for hunger and food insecurity is income poverty. At its best, charitable food distribution offers a temporary band-aid for the acute, short-term lack of food. The basic problem from the viewpoint of ethics is that charitable operations do not guarantee the right to food, a right that is derived from the Declaration of Human Rights. In her examination of the ethical approaches to world hunger, Onora O'Neill (1987) pointed out that talk about rights is often incomplete due to the neglect of the question of who bears the corresponding obligations to fulfill those rights. Charity organizations are not obligated "to respect, protect, and to fulfill" the right to food (Ziegler et al. 2011) as the states are.

Conclusion

Food assistance is a practice of helping people or households who cannot obtain food on their own.

With reference to universal human rights and the right to food, states can be held responsible for respecting, protecting, and fulfilling this right. Since household-level food shortages often indicate broader economic or social problems, states typically conduct their food assistance practices as a part of the broader social policy framework, and it is common to provide this assistance in a financial form.

There are also new ways to approach and organize the food assistance practices. In Brazil, for example, there are public food banks run by municipalities as public institutions and supported by a federal government program. These public operations include subsidized popular restaurants and community kitchens, and they act as a part of a government policy to fight against hunger. The public food bank model differs from charitable food delivery. State-based public food banks could be obligated to help all the needy equally and the quality and amount of delivered food as well as environment and accessibility of distribution sites can be controlled. Some practices, especially the community kitchens and restaurants, also promote the inclusion and agency of the people who use the services, so that the food assistance recipients are not merely passive recipients but active citizens. (Riches and Silvasti 2014).

Often the state policies fail to guarantee the food security of all citizens, and there are food insecure households both in developing and developed countries. These people rely on the existence of food charity, food deliveries conducted by private or nongovernmental actors like charity organizations or the church. There are various ways to exercise food charity, and the relevant ethical considerations depend on the practices in question. The argument that we have a moral obligation to alleviate the suffering of others when we can is a common one in ethics. For the well-to-do people, participating in the food charity activities is one way to meet that individual obligation. On the other hand, the whole (need for the) existence of a food charity practice based on voluntary acts is something that can be criticized from a more systemic normative viewpoint.

The right to food is a human right. Charity food, by contrast, is not an entitlement but a gift; recipients have no legal rights to donations, and charities do not offer legitimate access to all citizens equally. It has also been argued that the positive cultural status of charitable work normalizes poverty and legitimates personal generosity as an answer to major social, political, and economic disorder manifesting as hunger or food insecurity (Riches and Silvasti 2014). This implies that the flip side of charity is decreasing social justice (Poppendieck 1998). Food charity does not eliminate the structural root cause of food poverty, income poverty. The moral tragedy is that while the provision of food for hungry people can be considered an individual level moral obligation, it also easily leads the attention aside from the elimination of the root causes of food poverty. As a result, the ethical considerations regarding food assistance and food charity can and perhaps should take place at two different levels: one that acknowledges the existing realities and the other that aims for steering the societies in a direction where food charity practices would not be needed in normal circumstances.

Food Assistance and International Trade

[Food aid](#)

Introduction

The donation and delivery of food assistance is widely viewed as a purely humanitarian endeavor; however, the historical motivations for donor-countries' food assistance policies are often self-serving. Also, food assistance can generate negative commercial and humanitarian effects in recipient-country markets. Such complications

have led to the entanglement of international commercial trade policies and governing architectures with the humanitarian domain of food assistance. Several decades of debate and analysis of these issues have been productive, however, and food assistance policies have evolved to better serve those most in need.

It is worth making a clarification on terminology before proceeding. “Food aid” has traditionally been used to describe “the international sourcing of concessional resources in the form of or for the provision of food” (Barrett and Maxwell 2005). Recent innovations in the way that these resources are provided have led to the use of “food assistance” as a more general descriptor that includes cash-based donations and food vouchers, in addition to traditional in-kind food shipments. This entry uses food assistance as a general descriptor and specifies otherwise when referring to in-kind commodity shipments or other forms (cash, vouchers) of assistance.

Donors

The overlap of food assistance and international trade dates back to the first national programs of the 1950s. Canadian and US domestic farm support programs generated surplus production, and national governments sought markets into which these commodities could be disposed without triggering negative price effects in home markets. US food assistance programs, in particular, were entangled with US exports because most assistance shipments were made under the authority of the United States Department of Agriculture (USDA) instead of the United States Agency for International Development. Farm support programs that were paid for by the USDA generated large public stocks of cereal grains that had to be either stored at public expense or disposed of in external markets where US exports would not normally compete. Public Law 480 was established to govern US food assistance policies, and Title I of this program was the largest outlet for US commodities for several years. Food assistance through Title I served two policy objectives: to dispose of public stocks and to develop

prospective markets for future US commercial exports. Policymakers believed that providing free, or discounted, cereal grains to consumers in developing countries could condition local tastes for US-produced cereal commodities and create future export markets for US producers. The ethics of attempting to change traditional tastes through such means are unclear, but there is no convincing evidence that this strategy was successful (Barrett et al. 1999). The market development objective of US food assistance has subsided in recent years, and most US assistance is now channeled through Title II (commodities that are provided to meet humanitarian needs). A large share of US food assistance was historically sold on concessional terms instead of provided in grant form. Such concessions often took the form of export credit guarantees that offered favorable financing terms to buyers. This practice has been abandoned, and all US shipments have been in grant form in recent years (World Food Programme 2012).

Other major donor countries also used their food assistance programs to unload domestic agricultural surpluses. The European Union’s (EU) Common Agricultural Policy (CAP) provided generous support to producers and generated large domestic surpluses. A large share of European Commission (EC) food assistance was drawn from these government-held stocks in the early years of EC programs.

Japanese food assistance programs are closely linked to international trade policies because of the country’s obligations under the World Trade Organization (WTO) Agreements. Japan agreed to allow a minimum volume of rice imports after the implementation of the Uruguay Round Agreement on Agriculture (URAA) in 1995. This commitment was quickly followed by a jump in in-kind donations of rice from zero to an average of 185,000 mt per year (World Food Programme n.d.) thereafter. Japan appears to be using its in-kind food assistance shipments as an outlet for some of the rice that it has agreed to import under its WTO agreement obligations, instead of allowing the imported rice to enter the Japanese market.

Canadian food assistance was traditionally not linked to international trade policy objectives, but

procurement policies were captured by domestic agricultural interests. The Canadian Treasury Board (responsible for funding official Canadian food assistance programs) tied procurement of donated commodities to the Canadian Wheat Board. The Canadian International Development Agency (responsible for allocating Canada's official food assistance budget) estimates that they paid substantially more to the Canadian Wheat Board than would have been the case if commodities were purchased on international markets (Canadian International Development Agency 1998). The fallout of this tying program was fewer, and smaller, donations from Canada.

Food assistance policies that tie commodity procurement to donor-country agricultural interests amount to implicit subsidies to domestic producers and processors. The result of such policies is that a portion of governments' international development budgets are used to support domestic agricultural interests. The ethics of such practices are questionable, and the debate over these policies has led to important changes in food assistance policies in most donor countries. Most donors have weakened the links between international food assistance policies and domestic agricultural interests. Canada completely untied its food assistance procurement, and almost all food that is purchased with Canadian funds is now purchased in local or regional markets. The EC also provides almost all of its food assistance in cash to be spent in local and regional markets.

The USA is the important exception to this trend. Changes in domestic farm support programs have stemmed the acquisition of public stocks, but procurement remains closely tied to domestic sources. The value of US food assistance programs – approximately US\$1.7 billion in 2010 (Ho and Hanrahan 2010) – is not large enough to provide significant subsidies to US primary agricultural producers, but there remains an “iron triangle” (Barrett and Maxwell 2005) of interest groups that are motivated to preserve the current system. The first point on this triangle is a corps of US processing companies that submit proposals in response to government tenders for commodities. These requests are mostly limited to

US-based firms and are generally uncompetitive. The Guardian (Provost and Lawrence 2012) reports that three firms provided 70% of US food assistance commodities in 2010–2011. The second point consists of US-based shipping companies who benefit from uncompetitive granting of transport contracts that are restricted to US-flagged vessels. Shipping costs on such contracts are high and are implicit subsidies to US shipping firms (Williams 2006). The third point on the triangle consists of NGOs that receive in-kind food assistance as a form of budgetary support from the US government. These NGOs sell the food (“monetize”) in developing-country markets and use the proceeds to support their activities. There is concern among these NGOs that reductions to in-kind donations would not be offset by higher cash donations; congressional leaders and lobby groups have stated that they would not support the continuation of current budgetary support levels for food assistance programs if the restrictive tying policies were relaxed. Smaller shipments from the USA would significantly affect global food assistance flows because the USA provides more than one-half of all commodities (by volume) in most years.

The transition from in-kind to cash-based food assistance has led to a remarkable shift in procurement patterns. The share of food assistance purchased either locally (in recipient countries) or regionally (in neither donor nor recipient countries) has jumped from approximately 10% to 70% over the past 20 years – this share is above 80% if US shipments are excluded. Locally and regionally procured food assistance (LRP) provides flexibility to food assistance organizations and is often preferred to donor-country procurement for several reasons. First, locally procured food can typically be transported to recipient regions much faster than donor-sourced food. Second, it can be easier for donor organizations to meet their commitments to provide “culturally appropriate” food if commodities are purchased near recipients. This commitment is viewed by many implementation organizations as an ethical response to the historical use of food assistance as a tool to change local tastes in hopes of developing export markets. Finally, LRP commodities can

be cheaper than food that is purchased through uncompetitive bids in donor countries.

Local and regional procurement has the potential to generate temporary demand surges in small markets. Such demand, though beneficial for traders and local producers, can increase local prices and reduce consumers' access to food. Most food assistance organizations are cognizant of this risk and make efforts to mitigate negative effects. Concerns about contract defaults and quality/safety standards have prevented food assistance agencies from buying from smallholders and local markets (Tschirley and del Castillo 2007); most LRP contracts are struck with commercial traders.

The movement to LRP has been paralleled by a shift in the categories of food assistance being delivered. Program food assistance is traditionally bilateral aid; this is donated to recipient-country governments and then sold in local markets; proceeds provide budget support to the recipient government. Project assistance is also sold in recipient markets (monetized), and proceeds are used to pay for development projects. The share of food assistance volume that is made up by program and project aid has fallen from approximately 85% to 25% over the past 20 years (World Food Programme n.d.). Emergency food assistance, which is delivered in periods of humanitarian crises, has become the primary type of food assistance and now accounts for almost three-quarters of shipments by volume (World Food Programme n.d.). This transition is the result of evolving priorities in donors' food assistance policies. Program food assistance was historically the largest category and was used primarily as budget support for recipient-country governments. Such donations often reflected strategic political and diplomatic, instead of humanitarian, concerns. The most prominent example of this was the US donation of over 3 million metric tons (mt) of grain to Russia in 1993 and 1999 to encourage stability and strengthen ties with the new leadership. The increased use of emergency food assistance reveals the stronger emphasis that donors now place on the humanitarian objectives (i.e., reducing the incidence of acute hunger) of food assistance. Donor interests (such as export

market development, strategic political concerns, and domestic agricultural interests) in allocating food assistance are becoming relics of the past, with the notable exception of US procurement policies.

Recipients

The inflow of noncommercially imported food, as donated assistance, has the potential to disrupt local markets in recipient countries. Such disruption can take the form of lower domestic prices and reduced imports. Nobel Laureate Theodore Schultz (Schultz 1960) questioned the ethics of disposing of US agricultural surpluses without regard for potential negative developmental effects in recipient markets. He formalized the potential negative effects on domestic prices through the description of disincentive effects on local producers; local producers may respond to lower prices by scaling back domestic food production. Surges of food assistance commodities can also displace commercial imports, thereby affecting trade flows. The potential for displaced commercial trade has framed much of the discussion about food assistance disciplines in WTO negotiations. The concerns about such effects are theoretically sound: an inflow of food will necessarily affect local market prices if it is not wholly additional consumption (i.e., the increase in food supply is not matched by an equivalent increase in food consumption). Observed income elasticities of food demand are less than one, so food assistance commodities cannot be wholly additional (Barrett and Maxwell 2005), and there will necessarily be price effects.

The magnitude of price effects depends on several factors, some of which have been investigated in empirical studies. Barrett et al. (1999) find that aid shipments do not significantly affect recipient-country production, but have a J-curve effect (initial decline, followed by longer-term increase) on commercial imports across a panel of 18 recipient countries. Other studies find mixed results, including negative production (Gelan 2007) and negative price effects (Tadesse and Shively 2009) in Ethiopia, and no significant

production effects in Swaziland (Mabuza et al. 2009). Such results cannot be generalized, however, because the effects of assistance shipments depend on the peculiarities of each case. A few broad lessons can be deduced, though. First, there is the potential for unintended negative consequences of food assistance shipments. Second, this problem is more likely to occur when commodities are monetized. Third, better targeting to those most in need reduces negative market price effects because such consumption is likely to be more additional than if the food is distributed to relatively better-off consumers. Recent developments in most donors' policies have reduced the probability of significant negative side effects. Implementation organizations are better targeting those most in need, and most donors (the USA notwithstanding) no longer allow the monetization of their donations.

International Agreements

The first formal international mechanism linking food assistance and international trade was the Food and Agriculture Organization's Consultative Subcommittee on Surplus Disposal (CSSD). The CSSD was convened in 1954 to oversee donor-country practices in an effort to mitigate the displacement of commercial imports. Donors agreed to report donations to the CSSD and were encouraged to maintain "usual market requirements" in donor countries. Usual marketing requirements were operationalized by comparing current year commercial imports to a 5-year historical average. If imports fell below this average, then UMRs were not met. The CSSD had a commercial trade agenda, not a humanitarian agenda, and it did not affect the links between domestic agricultural interests and food aid policies in donor countries. Also, its guidelines were not enforceable and reporting requirements suffered from low rates of compliance.

The Food Aid Convention (FAC) was negotiated alongside the Kennedy Round international trade negotiations in 1967. Donor countries (current members are Argentina, Australia, Canada, EC, Japan, Norway, Switzerland, and

the USA) committed to provide 4.5 million metric tons of grain each year to developing countries. The FAC contained lists of acceptable commodities and formulae for calculating the commitments in different commodities (e.g., maize, rice, and wheat). The FAC, like the obligations of the CSSD, had no enforcement mechanism, and some members did not meet their donation obligations in some years. But, unlike the CSSD, the FAC was motivated by humanitarian concerns. The FAC is fundamentally apolitical in that it does not set any guidelines for how recipients are to be determined; allocation decisions are left to donor countries. The FAC was renewed several times between 1967 and 2011.

A new FAC (now called the Food Assistance Convention) has been negotiated and is scheduled to take effect in 2013. Some commentators had advocated for a change in the measurement of commitments that would increase the incentives for donors to provide micronutrients. Also, the increased popularity of cash and voucher-based assistance programs led some to advocate for a new method of calculating donor obligations based on value instead of volume (e.g., commit donors to inflation-indexed value contributions instead of volume contributions). This suggested change was not incorporated, and the new FAC bears close resemblance to past versions.

Food assistance first entered the WTO set of agreements in the 1996 URAA. The URAA contains disciplines on a range of trade-related policies that are enforceable through the WTO's dispute settlement understanding (DSU), but references to food aid appear only as guidelines and are not enforceable through the DSU. These guidelines call for shipments to be untied from domestic procurement and defer to the CSSD reporting procedures. These guidelines did not affect food assistance policies in donor countries; in fact, the reduction in domestic support payments that followed the implementation of the URAA probably had more significant effects on food assistance. Large public stocks are no longer prominent features of domestic support programs, so the pressure for unloading surplus commodities has lessened. The URAA remains the governing

agreement between trading partners related to food and agricultural products.

The ongoing Doha Development Agenda (DDA) round of WTO negotiations has been framed by the increased assertiveness of developing countries, many of whom felt that they did not receive the developed-country market access promised to them in the URAA. Developing countries have pushed hard for special and differential treatment in the implementation of new disciplines and for increased flexibility to increase tariff barriers (Special Safeguard Mechanisms) in the face of import surges. Despite the title of “Development Agenda,” the WTO agreements that are being negotiated fundamentally remain trade agreements, and there remain lingering concerns among competing food exporters that food assistance can displace commercial trade.

The DDA negotiations over food assistance can be understood through the lens of the ongoing dispute between the EU and the USA over export competition policies. US negotiators are seeking binding and effective disciplines on the EU’s use of export subsidies in agricultural industries. WTO negotiations are reciprocal, and EU negotiators are, in turn, pushing for disciplines on export credit guarantees that the USDA provides to consumer nations. The USA has, until recently, provided some food assistance to recipients under favorable credit terms instead of in grant form. The DDA negotiations have settled on the construction of a “safe box” for food aid that would be exempt from export competition disciplines. The most recent draft modalities to emerge from the DDA negotiations (World Trade Organization 2008) define this safe box as containing food shipments that are provided in response to an emergency declaration by the recipient-country government, the United Nations, or a relevant humanitarian organization. Shipments that do not meet the safe box criteria, with a few exceptions, would be prohibited and subject to disciplines on export subsidies or export credit guarantees.

Observers have raised concerns about the ethics of constraining food assistance shipments with an international commercial trading

agreement. Negotiators at WTO meetings are cognizant of these concerns, and draft modalities defer to humanitarian organizations with expertise in food security to determine when food assistance is needed. Such concerns may be immaterial, however, because it is unlikely that food assistance shipments will be affected by international trade agreements in the near term. Doha Development Agenda negotiations are stalled and are unlikely to be completed anytime soon. This means that the URAA will remain the document of record. Also, it is difficult to envision a situation in which a formal WTO case would be pursued against a donor country (Cardwell 2008). Negotiating countries are aware of the scorn that would be directed towards them if they were to pursue trade retaliation against a donor country. Negotiators also recognize that a WTO panel could consider the opinions of other interested parties when ruling on whether a shipment satisfied safe box criteria – it would not be difficult to find an interested party that could provide justification for a shipment *ex post*.

Other Issues

The food crisis of 2008 led to anti-trade policies in net food-exporting developing countries that generated a new type of problem for food assistance agencies. Governments in several countries imposed export restrictions on food in attempts to constrain domestic food price inflation – these restrictions included border taxes and export bans. Aid organizations, including the World Food Programme (WFP), reported that such policies threatened their ability to source commodities from LRP markets. The risk of encountering such barriers has been more relevant in recent years because of most donors’ increased reliance on LRP commodities. World Trade Organization disciplines on export restrictions did not apply to the types of policies that were implemented over the past few years (Headey 2010), and DDA negotiations have not addressed this issue. Several developed countries have proposed an agreement between exporting countries (outside the

auspices of the WTO) that would exempt non-commercial, humanitarian food from future export restrictions. Most net food-exporting developing countries oppose such an agreement on the grounds that they have ethical responsibilities to prioritize the food security of their own residents. The reality is that food assistance purchases would typically be too small to affect domestic prices in source countries, but such decisions are inherently political and it is likely that anti-trade policies of this type will remain unchecked.

The allocation of food assistance across recipients has been controversial since the first national programs in the 1950s. The seemingly ethical method of allocating limited food assistance resources across recipients would be to deliver food to those recipients whose marginal benefit is largest; that is, target those most in need. Identifying “need” in this context is a complicated task, but there is evidence that recipient need has not been the only, or even the most important, determinant of food aid flows. Studies have identified non-humanitarian factors as being important drivers of donor allocation decisions; these include colonial ties between donor and recipient (Nunn and Qian 2010) and geographic proximity (Neumayer 2005). There have also been reports of the provision of food assistance being used as a bargaining chip in negotiations between the USA and North Korea about nuclear technology. Conditioning the delivery of food assistance on anything other than recipient needs presents serious ethical questions about the role of international assistance – should vulnerable populations be captive to international political considerations? Such questions are, however, becoming less relevant in food assistance allocation decisions. Multilateral assistance (i.e., delivered through the WFP) is more responsive to need than bilateral deliveries, and emergency assistance is more responsive to need than program and project assistance. The shares of food assistance that are multilateral and are emergency have been increasing for several years.

The emergence of genetically engineered (GE) crops has forced international trade concerns into the humanitarian arena of food assistance.

There have been instances in which shipments of GE commodities were turned away in recipient countries, for example, Zambia’s refusal of GE maize from the USA in 2002. There are several ethical considerations in such cases. The ethical standard set by the Codex Alimentarius (a joint effort between the World Health Organization and the Food and Agriculture Organization to provide and guide international food safety assessments) is that international food assistance shipments should meet the national safety regulations of the donor country (CODEX Alimentarius 2010). This requirement is satisfied in the case of GE maize, which is widely produced and consumed in the USA. Genetically engineered maize was rejected in Zambia, however, based on claims of health concerns for Zambian recipients. Certainly, it is the prerogative of recipients to decide on the suitability of food for their own consumption, but such concerns should be weighed against the ethics of turning away food (which has been deemed safe by international organizations and several countries) during periods of humanitarian crises.

There is also a strategic international trade concern that underlies the decision to accept or reject GE commodities as food assistance. The EU maintains a *de facto* ban on the importation of most GE food products, and developing countries have expressed concerns that GE food assistance may comingle with their domestic production. Such comingling could contaminate otherwise non-GE exports that are bound for EU countries and jeopardize future contracts. The potential loss of export markets in the EU could be damaging for local producers, and the implementation of segregated supply chains is not feasible in many developing countries. The concern about contamination can be addressed by milling grains prior to delivery (thereby ensuring that GE whole grains are not planted in recipient countries), but this adds costs and reduces shipment volumes, *ceteris paribus*.

The debate over GE commodities in food assistance shipments has generated a spate of ethical accusations between donor countries and NGOs. Countries in the EU and some NGOs have accused the USA of pursuing markets for its GE

products by donating food grown from GE seeds. The reality, however, is that the donation of GE products from the USA is a function of USA tying policies, not market development objectives. Approximately 90% of US soybean and maize crops are grown from GE seeds (United States Department of Agriculture 2012), so countries that receive food assistance from the USA are likely to receive GE products. Segregation of GE from non-GE food in the USA before donating these commodities is not feasible, particularly in light of such products being approved for human consumption in the USA. Other commentators have accused EU member countries of unethically forcing their tastes for non-GE products on poor people in developing countries. Such criticism may be justified, but the real issue is the fear of lost commercial export markets. Widespread consumer rejection of GE products in EU countries is unlikely to change in the near term, and developing countries' decisions about accepting GE food may hinge on their assessments of the risk of lost export markets.

The importance of this issue in the future will depend on the adoption of GE technology in developing countries. Most donors, with the notable exception of the USA, have moved towards LRP for donated commodities, and GE adoption rates in many countries are below those in the USA (partly because existing GE technologies have been designed for use in temperate climates on crops that are commonly grown in the USA).

Summary

The provision of food assistance to those in need is viewed by many as an ethical responsibility for developed countries. Several developed countries have, to some degree, accepted this responsibility and agreed to provide commodities as part of their FAC obligations. The finer points of each country's food assistance policies begin to cloud the ethics of food assistance deliveries, however. National food assistance programs began as reactions to donor-country agricultural industry interests, not as humanitarian endeavors. Other

commercial interests (market development, displaced commercial trade) and political concerns (geopolitical considerations, colonial ties) became entangled with food assistance policies in the years that followed. This entanglement led to the presence of food assistance guidelines and disciplines in WTO commercial trade agreements.

There is good news, however. Most donors have significantly reformed their food assistance policies by untying procurement from domestic sources and by channeling more assistance through multilateral channels (i.e., the WFP). Food assistance serves the needs of the most vulnerable much better today than in decades past. The USA remains the main exception to this, which presents a dilemma for those advocating for change. The tying of US procurement to domestic sources reduces the effectiveness of the US food assistance budget, but financial support for these programs would fall if procurement were to be untied. The USA provides approximately one-half of global food assistance commodities, so such a loss would leave a large gap in the volume of resources available for humanitarian projects.

Introduction

Food Banks are nonprofit organizations whose main objective is to combat food insecurity by means of the distribution of food via intermediary entities. In some cases, although not always, this is surplus food which, if not donated, would become food waste. Although there are numerous types of Food Bank, the functioning of many of them depends to a large extent upon the work of volunteers. With a few exceptions, these are entities that distribute and/or deliver the food as and when it is received, that is, without processing it.

Various sources (Poppendieck 1999; Schneider 2013, p. 756) locate the modern origin of Food Banks in Arizona in the late 1960s. John van Hengel, who was volunteering at a soup kitchen in Phoenix, began soliciting donations of surplus food products picked up from grocery stores in the area. Then he decided to set up a warehouse where donated products could be stored for distribution to charities feeding hungry people in Phoenix. In 1976, the US Federal Government supported van Hengel's bank across the nation. Since the 1980s, Food Banks have become the fastest growing charitable organizations in the wealthiest countries of North America, Europe, and Australasia (Riches 2002, p. 649). In 1981, the first Food Bank was set up in Canada, the Edmonton Food Bank in Alberta, and the first

European Food Banks were introduced in France, Belgium, and Spain. The greatest expansion in Europe, however, occurred from the second half of the 2000s onward and in particular following the financial crisis (Riches and Silvasti 2014a). Many Food Banks are connected at a national, regional, or international level to support networks like *Feeding America* (USA), *Canadian Food Banking Association*, or *European Federation of Food Banks* which groups together 265 Food Banks in 23 EU countries, all of them linked with *Global Food Banking Network* (GFN) established in more than 60 countries of five continents.

With regard to their role in the countries of the Global North and especially in those where there exists a constitutional legal welfare system, the main controversial issues reflected in academic literature can be divided into three blocks.

Controversial Issues Regarding Food Banks in Wealthy Countries: Overview

A narrative has been built around Food Banks which presents them as capable of simultaneously offering a response to two problems: on the one hand, they constitute a partial solution to food waste, which has a significant economic and environmental impact, and, on the other, they contribute to reducing food insecurity.

According to the FAO (1996), food security exists when “all people at all times have physical and economic access to sufficient amounts of safe and nutritious food to meet their dietary needs and food preferences in order to lead an active and healthy life.” In the countries of the Global South, and in some of these in particular, large sections of the population are severely affected by food insecurity, but this is not the case in the countries of the Global North. In the latter, there is considerable amount of food available, so much so that in the EU, for example, one third of what is produced is wasted (EU COMMISSION 2015). But that availability does not guarantee that everyone has access to food. Fifty-five million EU citizens

cannot “afford to eat meat, chicken, fish (or a vegetarian equivalent) every other day” (Eurostat 2015).

In the institutional narrative, and to a large degree in public opinion and in the media, the actions of Food Banks are celebrated and their value reaffirmed, as social responses to food vulnerability. However, exhaustive analyses reveal the ambivalent nature of the phenomenon. The emergency relief that they provide is very important, but, at the same time, the dominant Food Bank model involves a series of shortcomings and potential risks in the medium and long term.

Set out below, and grouped into three blocks, are the critical reflections prompted by the dominant Food Bank model. The degree to which they contribute toward achieving the goals they pursue, namely, reducing food waste (first issue) and combating food insecurity (second issue), makes us question their contribution to alleviating food insecurity in the medium and long run.

First Issue: To What Degree Do Food Banks Contribute Toward Reducing Food Waste?

According to FAO (2013), every year around 1.3 billion tons of food is produced that is not consumed. An adequate distribution of food would facilitate improved access to food for all the inhabitants of the planet, but today most of that food ends up as food waste. The Food Banks collect, among others, unmarketable foods that are perfectly edible and safe, for example, food near its sell-by date, incorrectly labeled products, products not manufactured exactly as specified or with damaged outer packaging, as well as fruits and vegetables that do not meet market standards owing to their appearance, size, shape, or ripeness (Power 2015). If no alternative destination is found for these products, they are destined to become food waste.

However, Food Banks also handle products that have not actually been salvaged from food waste. Thus, they obtain food by means of major

public collection campaigns (in other words, products purchased in supermarkets) and also acquire perishable foodstuffs such as fruit, vegetables, eggs, and dairy products, with monetary donations. It cannot be said, therefore, that only totally altruistic donations are distributed, nor is it possible, in every case, to refer to the donated food as surplus. In some regions, moreover, they distribute food that has been acquired by governments or government bodies at an international level.

The proliferation of Food Banks in Europe, particularly since 2009, and the growing public discourse in favor of the latter are normalizing, rendering natural their presence and social function (Perry et al. 2014). But beyond an altruistic gesture, a model system is being institutionalized for the distribution and access to food which operates as an alternative to the market and is characterised by the lack of food autonomy of the people who resort to it. A critical reflection is imperative, giving food to those who need it is without any doubt an altruistic gesture that no contemporary society questions. But is charity all that wealthy societies have to offer to citizens suffering from food poverty? What is the medium- or long-term solution we want?

There are questions with regard to the benefits obtained by some of the donors that participate in the functioning of Food Banks. Since the 1970s, government programs have existed that stimulate donations by the agri-food industry via incentives like *tax relief*, and there are food groups whose origin is to be found in regulatory mechanisms of the agricultural markets. Meanwhile, through the European Union program “Fruit and Vegetables Aid Scheme,” withdrawn products are distributed in such a way that stabilize the prices of agricultural products. Furthermore, there is evidence that food donation to Food Banks is the source of numerous advantages. Sending surplus or waste food to Food Banks instead of to the rubbish dump avoids the expense that would be incurred in its elimination in the latter process, results in the tax deductions associated with donations, reduces storage and transport costs, and can serve to increase the efficiency of the entire supply and donation

chain, and the food industry’s support of Food Banks has a positive impact in terms of its corporate social responsibility, all of which represents a source of competitive advantage (Caraher and Cavicchi 2014; Silvasti and Riches 2014, p. 197; Booth and Whelan 2014).

Second Issue: To What Extent do Food Banks combat Food Insecurity?

The charitable work of Food Banks is on the rise due to, above all, the effects of the economic crisis, but when gauging the situation of the final beneficiaries, we find that the exact details of its real impact are not easily determined. Most of the organizations that distribute frontline do not have exact data with regard to the amount of food donated, and even when the data are available, confidentiality makes it difficult to access (Schneider 2013, p. 759). There also exists a quantity of food from Food Banks which, given the imminence of the sell-by date or storage problems, finds its way to institutions that do not specifically attend destitute persons (hospitals, nursing homes, or schools, among others).

Another question that prompts reflection is the fact that, in general, food aid functions as a form of income transfer. In other words, people living below the minimum income threshold and, therefore, lacking the resources economically to attend to their basic needs turn to food aid in kind so as to be able to devote their scant resources to nonfood needs. Along these lines, the question is also asked as to whether food donations are more effective than direct cash transfers to enable low-income households to satisfy their basic needs (Tarasuk and MacLean 1990, p. 331). Food charity is not designed to meet the dietary and general food requirements of the target population in particular (Silvasti and Riches 2014, p. 197). The reference criterion in its organization is effective administration of those food groups that are received at the banks. Meat and fish, as well as fruit and vegetables – whether fresh or tinned – are essential elements of a diet but are seldom present in charitable programs. Which is why academic literature associates this kind of

social aid, or at least some of its results, with a broad spectrum of negative impacts on health (Vozoris and Tarasuk 2003). Tarasuk and MacLean (1990, p. 332) also allege that institutional dependence on charitable food aid is in some circles a major obstacle to good health and, therefore, cannot be considered an efficient or appropriate response to severe and generalized food problems.

With regard to the actual system of functioning of Food Banks, Poppendieck (1999) lists seven fundamental problems with emergency aid, which she synthesizes with the expression “seven deadly ‘ins’,” some of which describe organizational and supply problems such as *insufficiency* (when the food available via donations is insufficient), *instability* (the donations, the voluntary work, and the financial donations are unpredictable and unstable), *inaccessibility* (the Food Banks are not necessarily located where they are most needed), and *inefficiency* (connecting people in need of food with the resources available has a very high cost). Others underline *inappropriateness*—because the distributed food is not in keeping with people’s preferences, religion, or health requirements—, and even *nutritional inadequacy* (because it does not satisfy the nutritional recommendations adapted to the needs of each person). In terms of its effects, Poppendieck also stresses the *indignity*, as resorting to Food Banks often causes shame and a sense of humiliation.

Continuing in a similar vein, it is important to note that people who depend upon food aid lose part of their freedom of choice and inherent human dignity, because they have to accept donated food irrespective of their needs and preferences (Riches and Silvasti 2014a, p. 9). They lack *food autonomy* (Escajedo San-Epifanio 2016). Within the psychosocial consequences of institutionalized dependence on charity, it should be borne in mind that the social stigma and the sensation of impotence associated with poverty are exacerbated by that dependence, as it eliminates the personal option in the process of acquiring food and users are degraded and humiliated by having to demonstrate their right to receive what are essentially society’s leftovers (Tarasuk and MacLean 1990, p. 332).

Third Issue: What Is the Appropriate Response to Food Insecurity? Charity or Rights?

There exists a moral imperative to reduce food waste given its socioeconomic, environmental, and ethical implications. Nor is there any doubt that the reduction of food poverty is imperative as a question of human dignity. Moreover, the scandalous numbers in both cases (food waste and poverty) evidence the urgent need for a response. The question is whether or not the strategies implemented, among them some models of functioning of Food Banks, in the first place, are appropriate for their objectives and, secondly, whether or not they may generate undesired collateral effects. In other words, the risk we run is that responding to what is urgent may prevent us from (also) taking care of what is important.

Millions of people all over the world receive food on a daily basis from charitable organizations. It seems reckless, then, to suppress the work of these organizations without offering some kind of alternative to those who currently depend on their help. Another question is whether charity is the answer deserved by those who suffer food poverty in food-secure environments. In the medium and long term, a human rights approach demands that food poverty is faced by guaranteeing an autonomous right to access to food and, therefore, not only by means of charity. In the same way, in the medium and long term, it is to be hoped that food waste is gradually reduced until it is minimized or even disappears. That is the most responsible solution in terms of economy and sustainability.

In this context, it is worth reflecting on one of the most frequent criticisms of Food Banks: their charitable nature. They are an example of the growing importance of charity in the context of an increasingly reduced Welfare State (Lambie-Mumford and Green 2015). As a rule, for the general public, in the view of Silvasti and Riches (2014, p. 204), charitable operations are easily understandable as practical and common sense responses, based on human compassion vis-a-vis the problem of hunger in homes. In this respect, an interesting reflection upon the USA, a country

with a long history of Food Banks and similar resources, is that of the author Poppendieck (1999): the proliferation of charity contributes toward the failure of society to really address poverty. Charity helps to relieve the pressure to achieve more relevant solutions, as it acts as a “moral safety valve,” reducing the unease provoked by visible misery. At the same time, it creates the illusion of an efficient action in which there are thousands of ways of participating. This culture of charity normalizes destitution and legitimates personal generosity as a response to a major social and economic dislocation. As De Schutter concludes (2013), the institutionalization of Food Banks is a testimony to the incapacity of public authorities to fulfill the right to food, and the dependence on them is symptomatic of a broken system of protection and the failure of the State to fulfill its obligations to citizens. There is no doubt that charity performs a social role, but it should not be a substitute for rights (Arbour 2006).

According to Riches and Silvasti (2014a, p. 9), a significant contradiction occurs between public legitimization of the charitable distribution of food and the strong and growing trend towards the institutionalisation and corporativisation of Food Banks in affluent countries. At the same time that governments minimise and depoliticise hunger and food poverty as a relevant social problem, the establishment of Food Banks is reinforced at a global level led by the *European Federation of Food Banks* (FEBA) and the *Global Foodbanking Network* in most rich countries in the OECD and rapidly developing economies. This latter reflection follows the main thesis of Riches’ 1997 work “*First world hunger. Food security and welfare politics*”, in which he analysed –from the food point of view- countries of a liberal welfare tradition, food exporters and food secure via national production and imports, suggesting that hunger in those countries could not be caused by the lack of provision of sufficient food and nutrients, but was rather a question of distributive justice and human rights.

That comparative analysis of countries illustrated the interrelation between the neoliberal public and social policies and the government’s

negation of growing hunger or domestic food insecurity (Silvasti and Riches 2014, p. 193). Fifteen years later, these authors explain in their study of twelve rich countries (Riches and Silvasti 2014b), that the intensification and the harmful impact of neoliberal economic ideology upon the most vulnerable citizens of wealthy countries and their right to food is even more apparent, especially in the wake of the recent global recession. In a parallel manner, food charity continued its expansion and consolidation. In a parallel manner, food charity continued its expansion and consolidation. Assigning a central role to the third sector as an agent of the State in the production and supply of “public resources” is also seen as a part of this project of neoliberal governments to discharge previously public responsibilities upon the market, nonprofit organizations, and individuals and in so doing transform the caring role of the State in society (Evans and Shields 2000).

Other authors highlight the fact that Food Banks have a useful part to play in minimizing dissonance: it is essential for politicians to implement potentially problematic policies and show that in spite of the essential welfare reforms they advocate, they will never abandon those unable to feed themselves and their children, and also essential for society in general, which can continue to function without difficulty in spite of terrible inequalities (Ronson and Caraher 2015; 86). Thus, while the illusion continues to exist that immediate food aid is available for people who cannot feed themselves, governments will be little disposed to evaluate the appropriateness of their welfare programs, and in addition, there will be little pressure from the population for them to do so (Tarasuk et al. 2014).

Hence the growing insistence that Food Banks perform an important function, but ideally it should be a transitory function. Food Banks may be care spaces that can potentially serve to articulate a recently emerged and not yet fully formed alternative to welfare called “in the meantime.” This may provide welfare and care, but it may be connected to anticapitalist changes on a larger scale. It is a question of highlighting the dimension that Food Banks have as an expression of

ethical and political responsibility. Food Banks provide a space in which positive and progressive virtues are exercised and in which staff and volunteers can find new forms of being “in common” with the excluded social groups with whom they do not normally coincide (Cloe et al. 2016).

McIntyre and his collaborators (2015) add that the original list of “ins” compiled by Poppendieck has become established with time. Furthermore, they found new “ins,” which added to the criticisms of Food Banks, particularly in terms of their consequences. The work of Food Banks may be inefficient (*inefficacy*) – the question as to whether or not Food Banks have achieved the goal of reducing food insecurity; it may not prevent *inequality* – which they create between different classes –; Food Banks make poverty *invisible* – the presence of Food Banks gives the impression that poverty is being managed and therefore it is not seen; their *institutionalization*, a process by which Food Banks become institutions, and their concern with sustainability replaces service to clients –; Food Banks, as an acceptable response to hunger, prevails over the right to food, thus *invalidating the rights* to food.

Clearly, the objective of the charitable organizations focused on the distribution of food is neither to weaken the welfare system nor perpetuate poverty. But if the effects of their actions are not carefully examined and corrected, particularly in the medium and long term, those unwanted consequences might ensue. Clearly, the objective of the charitable organisations focussed on the distribution of food is neither to weaken the welfare system nor perpetuate poverty. But if the effects of their actions are not carefully examined, particularly in the medium and long term, those unwanted consequences might ensue. Particularly, regarding the form of access to food, because food received as an act of charity ceases to be seen as a right, with negative consequence for the beneficiaries. Received food is not always the most appropriate in terms of nutrients or personal preferences and the form of distribution is not geared towards avoiding the stigmatisation or shame that may arise from receiving charitable donations.

Summary

In its varied forms, the expression Food Bank is employed to refer to nonprofit organizations that contribute to the battle against food insecurity via an administration of surplus food. Although there are many types of Food Banks, the functioning of many of them depends to a considerable extent upon the work of volunteers. Their ways of functioning and, in particular, the medium- and long-term collateral effects of some of their actions have prompted debate and reflection on Food Banks since the late 1990s. Among the questions posed are their effectiveness in the battle against food waste and poverty, and the definitions of the spaces for charity and human rights. Charitable distribution, if not articulated appropriately, may help to stigmatize and perpetuate poverty and leave in the hands of the third sector or even of corporations a responsibility which corresponds to public institutions.

Ethical consumerism; Political consumerism

Introduction

What do tuna, grapes, salt, and Starbucks coffee have in common? All these foods have been subject to consumer boycotts. A boycott can be understood as a refusal to purchase goods or services with the intent of changing some aspect of the good or service. For example, when Rosa Parks refused to give up her seat to a white person on the bus and was subsequently arrested and jailed, the citizens of Montgomery boycotted the Montgomery bus system to challenge the laws and practice of the system. Boycotts are “an attempt by one or more parties to achieve certain objectives by urging individual consumers to refrain from making selected purchases in the marketplace” (Friedman 1985, p. 97).

This entry begins with the origin of the term *boycott* and the role of boycotts as a political strategy in contemporary society. Drawing from *Consumer Boycotts: Effecting Change Through the Marketplace and the Media* by Monroe Friedman (1999), one of the primary scholars of consumer boycotts, a taxonomy of boycotts is presented. Here various food boycotts are discussed in context of stages of boycott actions, functions of boycotts, the focus of boycotts, and boycott characterizations.

Role of Boycotts in Contemporary Life

The word “boycott” has its origins in food production. In 1880, in County Mayo, Ireland, a retired British army captain, Charles Cunningham Boycott, sent his tenant farmers to work for a fraction of their pay. When the farmers refused, Boycott and his family attempted the work themselves but grew tired in a short time. Eventually, the farmers went back to work yet on rent day were served eviction papers from Boycott. The tenant farmers organized a “mass meeting at which they persuaded Boycott’s employees (his servants, drivers, and animal herders) to desert him and his family. Three days after this declaration of social and economic ostracism, the term “boycott” was coined by [Father John] O’Malley” (Friedman 1999, p. 6).

As the Montgomery bus boycott was designed to target the practices and policies of the Montgomery Bus Line, many food boycotts are designed to influence one of the organizations or corporations that are involved in the production and/or distribution of food. In some cases, such as the Delano Grape Strike and the resulting boycott of table grapes, food boycotts are less about the food itself; instead, food becomes the symbol of the contested practice, policy, or ideology. As Friedman (1999) demonstrates, boycotts play an “important social justice role in American history” (p. 3). Recognizing the power of boycotts, Cesar Chavez explained, “boycotts are better than elections because the polls never close and you can vote more than once” (UFW Press Release).

The boycott and other consumption-oriented strategies are not without their criticisms. Bauman (2007) explained the rise in political disengagement as a “collateral causality” of rampant consumerism. (For more discussion, see Robert Putnam’s *Bowling Alone*.) Summarizing this research, Simon (2011) explained, “As forces of buying and selling spilled into every corner of American life, they narrowed . . . conceptions of citizenships. Politics, like consumption, became about me, about how something or some policy created immediate and material benefits, not about the larger community” (147). Brown (2003) argues, “The body politic ceases to be a body but is, rather, a group of individual entrepreneurs and consumers.”

Focusing on the potential power of a popular consumer pastime, Zukin (2004) suggests that engaging in political and electoral debate in the public sphere has been replaced by shopping. Through both purchasing and refusing to purchase, consumers communicate their presence in the marketplace. Moreover, their participation in the marketplace, and the flavor of that participation (e.g., which brand of coffee they buy), conveys ideals and values. As values such as justice and equality in society are often linked to consumer brands through marketing and advertising campaigns, the consumption of such brands acts as a “vote” for the company’s image and a definition of such values (Klein et al. 2004). This perspective suggests that consumers hold power to

enact conceptions of justice and equality through the power of their dollar. During the 2016 presidential election, for example, political sentiment was expressed by boycotting the Trump brand. Fashion retailers, Nordstrom.com and Nieman Marcus, discontinued selling Trump products, and some boycotted Miller Coors because the board member, Peter Coors, openly supported Trump Ethical Consumer. Echoing Cesar Chavez’s belief in the power of boycotts, Simon (2011) asserts, “boycotts are about leverage and about being heard; they are about the practice of political power. [As] boycotters urge fellow shoppers to think about the implications of their purchases . . . they attempt to leverage—and thus acknowledge—consumer power” (p. 152).

Taxonomy of Consumer Boycotts

This taxonomy is based on the work of Friedman (1999) and will discuss the following elements of consumer boycotts: stages of boycott actions, functions of boycotts, the focus of boycotts, and boycott characterizations.

Stages of Boycott Actions

When people begin considering a boycott solution, they embark on a potential four-step process to take them from idea to action. The decision to initiate a boycott, crafting a persuasive and compelling press release, planning the details,

gathering public support, and the implementation of a boycott are steps of a progressive process designed to put pressure on the target organization to comply with the demands of the boycott organizers. While not all boycotts move through the following four steps, they typically escalate in the following fashion with the first being the mildest action and to the latter being the most militant. Although this model may not have been conceptualized to explain the actions of individuals, it can, with some adjustments, be applied to both large-scale group boycotts and the actions of an individual. The following case in point describes the progression of the United Farm Workers (UFW) 2005 boycott of Gallo Wines (Table 1).

The Organizational Boycott: UFW and Gallo Wines

The UFW exemplifies a type of organization whose past success with action-taken boycotts has come to represent considerable force, organizational skill, and political power. When the UFW announces that they are considering a boycott, the target group often responds. In the case of the 2005 boycott of Gallo Wines, the boycott was short-lived, lasting only 3 months. When the UFW was considering a boycott of Gallo Wines due to labor issues, they began making the intention to boycott the public with a press release and show of support. Nearly a year before the start of the boycott, UFW President Arturo Rodriguez showed up at the City Hall in Los Angeles to

Food Boycotts, Table 1 Stages of boycott actions

Stage of actions	Description	Case in point
Action-considered	Press release that a boycott action is under consideration	UFW President Rodriguez delivers a petition with 25,000 signatures (Press Releases: New Gallo Boycott Kickoff Media Packet 2005)
Action-requested	Boycott is called	“No Gallo” boycott is announced
Action-organized	The details of the steps and procedures are given	Media Packet is released and supporters are directed to www.gallounfair.com for details about how to support the boycott
Action-taken	The boycott occurs	United Farm Workers (UFW) boycott of Gallo Wines (1973–1978 and June–September 2005) and Charles Krug Mondavi Wines (2006–2008) Delano grape strike/grape boycott organized by UFW and Cesar Chavez (1965–1970)

display petitions with 25,000 signatures pledging to boycott Gallo Wines unless a “fair and just” contract is negotiated (Press Releases: New Gallo Boycott Kickoff Media Packet 2005).

Moving to the next stage, action-considered, in June 2005, President Rodriguez officially called the “No Gallo” boycott via rally and march through San Francisco. Calling for a boycott is typically communicated via a press release and corresponding media coverage. In the action-organized step, specific plans for carrying out the boycott are given. The UFW made fliers which summarized the issues at stake, what they wanted consumers to do (i.e., exactly what wines to boycott as Gallo owns and produces under multiple labels), and a phone number to call with questions. The final step of course is to carry out the boycott which the UFW did, until September 2005 when they and Gallo ratified a 3-year contract giving workers pay increases and other benefits.

Inspired by the current #MeToo movement and a history of successful boycotts in support of farmworkers, the Coalition of Immokalee Workers (CIW) is calling for a boycott of the fast-food chain, Wendy’s. In 2011, the CIW launched the Fair Food Program (FFP) and was successful in ending sexual assault and other human rights violations in the \$650 million Florida tomato industry. According to the CIW, “By harnessing public awareness and the purchasing power of more than a dozen of the world’s largest retail food companies, the FFP has radically transformed working conditions for tens of thousands of farmworkers and has been recognized for its unique success by human rights observers from the White House to the United Nations. Today, the FFP extends to seven states and three crops, and all the major fast-food companies – McDonald’s, Burger King, Subway, Taco Bell, KFC, and Chipotle – are on board. Except Wendy’s.” (<http://ciw-online.org/blog/2018/02/why-we-are-fasting-2/>). To protest Wendy’s refusal to participate in the FFP, the CIW, along with its allies, launched the **5-day Freedom Fast** outside the Manhattan hedge fund offices of Nelson Peltz, Wendy’s largest shareholder and Chair of its Board of Directors. The goal of the Fast is to put

pressure on Wendy’s to “join the rest of the fast-food industry in supporting the Fair Food Program’s groundbreaking worker protections, and [to] protest the ongoing human rights abuses faced by workers in Mexico’s produce industry where Wendy’s currently buys its tomatoes.” (<http://ciw-online.org/blog/2018/02/why-we-are-fasting-2/>).

The Individual Boycott: Boycotting the Meat Industry

When an individual considers the personal decision to participate in a larger boycott, they too may progress through the four stages, albeit not so publicly. The popular slogan from PETA, “Go Veg,” represents the ideology and corresponding dietary practices which boycott the entire meat industry. While the refusal of vegetarians to purchase or consume meat products may be based on many individual motivational factors, such as concern for the treatment of nonhuman animals, health reasons, ethical considerations, or religious beliefs, the effect is the same: a boycott of the meat industry. Or in the case of vegans (people who refuse to consume all products containing nonhuman ingredients), their actions create boycotts of the dairy, leather, and wool industries as well.

Individuals considering the decision to be a vegetarian and participating in a larger boycott of the meat industry, for example, will probably think about this alternative diet before making the decision to “Go Veg.” He or she might consider choices by reading about the health benefits, reflect on how this new diet may or may not affect their daily life, or consider the ethical implications of their choice. If the decision is based on a response to a particular situation, he or she may write the offending organization and tell it that unless it rectifies the situation, one’s consumer support will be withdrawn. Next, they may tell friends and family to gauge the level of social support they will have for their decision. The third step in the process involves formulating a plan to carry out a successful boycott. For the individual, this may mean finding answers to the

Food Boycotts, Table 2 Primary functions of boycotts

Boycott functions	Description	Case in point
Instrumental	Boycott organizers attempt to achieve practical and material ends. Obstructionist boycotts are often instrumental	Cracker Barrel boycott (1991–2002) Southern lunch counter sit-ins (1950–1960s)
	Boycott organizers communicate frustration through symbolic acts	Starbucks boycott (2001)
Expressive	Surrogate boycotts are often expressive	

questions: “What will I eat if I give up meat?” “Where will I do my grocery shopping?” “Will I hurt my grandmother’s feelings when I won’t eat her traditional turkey at the family Thanksgiving meal?” “Is it alright that my choice will affect what others eat?” By finding solutions to these practical and ethical problems, the person arrives at a practical plan for carrying out their meat boycott. The final step, of course, is the action of giving up meat.

Primary Functions of Boycotts

While boycotts may fulfill more than one function, they usually contain a primary function. Those that are instrumental are designed to achieve practical ends, such as the change or implementation of a policy or behavior. Instrumental boycotts are often obstructionist. Expressive boycotts are often short-lived and are a means for venting frustration. Surrogate boycotts fall under this category (Table 2).

An Instrumental Strategy: The Obstructionist Boycott

Obstructionist boycotts operate by placing an obstruction between the consumer wishing to purchase a given product or service and the product and service itself. When carried out effectively, a

physical barrier is created to make obtaining the good or service difficult or impossible. Common obstructionist tactics include sit-ins, stand-ins, call-ins, mail-ins, and die-ins. However, what if the corporate target of the boycott is innocent of the charges brought by the boycott organizers? Or what if that corporate target is unable to defend themselves against such accusations or make adequate changes to the policy, product, or service under attack? These are some of the ethical questions surrounding obstructionist boycotts.

While not a boycott of the food itself, the lunch counter sit-ins in segregated Southern restaurants in the 1950s and 1960s are examples of this type. As the black protesters took up space at the lunch counter, they effectively used themselves as barriers between other potential customers and the lunch counter. Similarly, in 1991, the Tennessee Gay and Lesbian Alliance and the Queer Nation called for a boycott of the Cracker Barrel restaurant chain for its antigay and lesbian policies and the firing of some gay and lesbian employees. Participants in the boycott would engage in “slow-down sit-ins” where large groups of protestors as “customers” would go into the restaurant at peak times such as Sunday brunch or dinner, take up as many separate tables as possible, place a minimum order (e.g., a cup of coffee), and occupy the table for 2–3 hours (Friedman 1999, p. 150). In 1992, Cracker Barrel claimed that it was an equal-opportunity employer yet refused to rehire the fired employees or add sexual orientation to its nondiscrimination policy; thus, the boycott continued. It was not until 2002 when the shareholders of Cracker Barrel’s parent company voted to add sexual orientation to the non-discrimination policy was the boycott terminated.

An Expressive Strategy: The Surrogate Boycott

One of the most extreme examples of a food product and company as a symbol of protest as opposed to being the literal focus of the boycott is the 2001 boycott of Starbucks coffee. After a traffic violation, Aaron Roberts, a 27-year-old African-American man, was pulled over by two

F

white police officers. Roberts ended up dead at the scene, shot by one of the officers. Reverend Robert Jeffery believed Roberts' shooting to be the result of the Seattle Police Department's unofficial policy of "shoot first, cover up later" when dealing with young black men. Frustrated by the actions of the police in relation to the African-American community, Jeffery called for a boycott of Starbucks coffee. What's the connection between Starbucks and the death of Roberts by the Seattle Police Department? The power of surrogate boycotts.

In a surrogate boycott or indirect action, "a protest group finds itself dissatisfied with the public policies of a city state or foreign nation and acts upon its feelings by boycotting surrogates (the business firms operating in the geographic area" (Friedman 2001, p. 237). As with the case of Reverend Jeffery and Starbucks, the decision to launch a surrogate boycott often speaks to the disenfranchisement and frustrations of citizens to make effective change in the democratic process: "consumer actions increase when politics lose traction" (Simon 2011, p. 146). Boycotts, according to historian Dana Frank (2003), "fill a void where there aren't social democratic regimes." The Starbucks boycott suggests there is a shift of power from formal politics to consumer politics, "as if citizens have out-sourced their politics from the voting booth to the supermarket" (Simon 2011, p. 147).

But surrogate boycotts are not without ethical costs. Is it morally just to link Starbucks with the killing of Aaron Roberts? What about the costs of the boycott to not only Starbucks but the secondary targets, such as the suppliers of coffee or cups? According to Garrett (2001), "corporate executives who have experienced the force of this tactic have several strong reservations about the morality of boycotts" (p. 19). These include potential excessive power of the boycott and a restriction of consumer choice (Garrett 2001, p. 19).

Primary Boycott Focus

Depending on the primary function – instrumental or expressive – of the organizing group and how far they progress along the stages of boycott actions,

boycotts typically fall into one of two categories: media- or marketplace-oriented. As all boycotts depend on media outlets to grow and survive, the distinction here is on the *primary* focus of the boycott: where most of the action occurs, what strategies for change are utilized, and physical locations of actions. When a boycott stays at the action-considered or action-requested stage, the boycott occurs primarily in the media as boycott organizers attempt to place public pressure generated by media attention on the target of the boycott. Press releases and highly visible protests are utilized to create public awareness and support. Because of the need for public attention, media-oriented boycotts tend to occur in visible and easily recognizable locations such as in front of the target organization's headquarters, corporate sign, or logo. When a boycott progresses to the stages of action-organized and action-taken, the primary focus for action is the marketplace as boycotters are attempting to influence the bottom line of the target organization. Typical here would be for the boycotters to protest in front of a local restaurant that is part of a larger national chain to persuade potential customers not to dine there (Table 3).

Food Boycotts, Table 3 Primary boycott focus

Orientation	Description	Case in point
Media-oriented	The primary focus for action-considered and action-requested boycotts. Use of press releases and protests in a visible and recognizable local	PETA's McCruelty and Kentucky Fried Cruelty campaigns
Marketplace-oriented	The primary focus for action-organized and action-taken boycotts. Use of protests in places of large consumer traffic	The March to Dandi (Salt Satyagraha) 1930 Vegetarian boycott of meat industry Vegan boycott of meat and dairy industries as well as all products made from nonhuman animals

Media-Oriented: Kentucky Fried Cruelty

In response to the cruel conditions facing the one billion chickens killed each year by Kentucky Fried Chicken, PETA launched the “Kentucky Fried Cruelty” campaign and boycott in 2003. Since then PETA has held over 12,000 protests where activists have “crawled into cages, tied on bikinis in the freezing cold, walked around on stilts, and “slaughtered” and “burned” an effigy of Col. Sanders” (PETA 2012). Adding the weight of celebrity endorsements to this campaign, PETA has garnered public support of the boycott from His Holiness the Dalai Lama, the Reverend Al Sharpton, Dr. Cornel West, Alice Walker, Smashing Pumpkins, and the Black Eyed Peas. While the goal is certainly to effect change in Kentucky Fried Chicken’s treatment of chickens while they are alive, the primary focus of PETA’s media-savvy activities is to keep the issue in the public sphere and focus negative attentive and pressure on KFC.

Marketplace-Oriented: Salt War

Using the act of boycotting as part of the larger political and moral philosophy of non-violence, Mahatma Gandhi led the salt war as part of his lifetime quest to foster Indian Independence. The choice of salt was as much strategic as it was symbolic for Gandhi. As the need for salt cut across all regional, class, and ethnic boundaries in India, the focus on the salt tax did not have a polarizing effect on a diverse Indian population. And as the salt tax hit hardest on the lower class, this struggle symbolized the inequity that resulted from British colonial rule.

The salt march or Salt Satyagraha (truth force) began because of a salt tax that was imposed by the British government on the sale of salt. Moreover, the British government had a monopoly on salt, legally forbidding anyone else to produce or sell salt. On March 2, 1930, Gandhi wrote to Viceroy Lord Irwin asking that he amend the salt tax. When the request was not met, Gandhi and 78 male Satyagrahis from his Ashram in

Sabarmati began the 230-mile, 23-day walk to the seaside village of Dandi. Along the way, villagers stopped to watch the procession and many more joined in. On March 6, 1930, Gandhi picked up some mud, boiled it in saltwater, and produced illegal salt (Graham 2012).

Following his example, Gandhi invited others to make and sell their own salt and continue the war on the British salt tax. (A pinch of Gandhi-made salt sold for 1600 rupees or approximately \$750.) All across India, people produced and sold the illegal mineral with roughly 80,000 people being jailed for their actions. Although Gandhi asked only men to participate in the March, many women participated. This was significant as it marked the first time that women participated in the struggle for Indian Independence (Chatterjee 2001). Just days prior to his next planned action, a raid of the Dharasana Salt Works, Gandhi was arrested and jailed. The Salt Satyagraha continued until Gandhi’s release nearly a year later. Upon his release from jail, he participated in negotiations with Viceroy Lord Irwin resulting in the Gandhi–Irwin pact.

Boycott Characterization

Depending on whether or not they support or discourage consumer spending, a boycott can be positive or negative. Positive boycotts are a sort of “blacklist” and encourage consumers form purchasing the targeted good or service. Negative boycotts function as a “whitelist” and support the consumption of a particular good or service (Table 4).

Food Boycotts, Table 4 Boycott characterization

Quality	Description	Case in point
Positive	The refusal to purchase or consume a specific good or service	Tuna boycott (1988–1990)
Negative	The choice to purchase or consume a particular good or service. Also called a “boycott,” “girlcott,” or a “procott”	Buy Fresh, Buy Local (2002–present)

The Positive Boycott: Creating “Dolphin-Safe Tuna”

In response to a practice borne in the 1950s which has killed over seven million dolphins in the last four decades, the International Marine Mammal Project (sponsored by Earth Island Institute) organized a consumer boycott of tuna in 1986. The practice in question involved the intentional chasing down of dolphins and using purse seine nets in the hunting for commercial tuna. When biologist Sam La Budde got a job on a Panamanian shipping boat and secretly shot a film showing dolphins dying in tuna catching nets in 1988, he helped bring significant public awareness and support to the boycott. The boycott was further supported when the film was shown to a Senate subcommittee. Two years later, StarKist tuna (then owned by Heinz) announced that they would no longer buy tuna caught by methods that would cause harm to dolphins. Bumble Bee tuna and Chicken of the Sea quickly followed the lead set by StarKist. As further evidence of the boycott’s success, the “Dolphin-Safe Tuna” label was created and placed on all cans of tuna which followed dolphin-safe practices. Yet, despite the fact that this was a successful boycott as it significantly reduced the number of dolphins killed in the harvesting of tuna, in September 2011, the label was found to violate the World Trade Organization (WTO) (Tucker 2012).

Led by Casson Trenor of Greenpeace, a tuna boycott is under way to reform the tuna industry yet again. Currently, much canned tuna is skipjack and is caught using fish aggregating devices (FAD). To fish with an FAD, a buoy is cast into the water off of a boat. For small fish, the FAD acts as a barrier from larger fish. Eventually, the area around the FAD becomes a small but dense ecosystem as larger fish have discovered the fertile hunting grounds. Many of the FADs are equipped with radios and signal the boats when the fish population is high. Boats return with large purse seine nets and take in the targeted skipjack along with everything else in the vicinity – sharks, sword or marlin, young yellowfin and bigeye tuna. In September 2011, the Congressional representative from American

Samoa Eni Faleomavaega showed support for Greenpeace and called for a full ban on FADs. He further asked Americans to refrain from buying any products from Chicken of the Sea or Bumble Bee (Bittman 2011). Greenpeace is also calling for a boycott of Bluefin tuna which is served in some sushi restaurants in the United Kingdom. Greenpeace argues that the Bluefin tuna will soon be extinct.

The Negative Boycott: “Buy Fresh, Buy Local”

The ongoing “Buy Fresh, Buy Local” campaign is an example of a negative boycott. Negative boycotts are not boycotts at all but their consumption-oriented counterparts, also referred to as a *buycott*. A buycott encourages the purchase and/or consumption of particular goods or services, for example, “Buy American.” While the original focus was on produce and local farmers markets, the “Buy Fresh, Buy Local” campaign encourages community members to purchase all locally made products and to patronize locally owned establishments. For some, buycotts are preferred over boycotts because of their positive rather than punitive tone.

Conclusion

The decision to boycott a particular food is often a symbolic choice, such as Gandhi’s choice to use salt to represent the cruelty of British colonial rule or Cesar Chavez’s focus on table grapes to stand for the plight of farm workers. These symbolic functions can be understood by looking at the stages and primary focus of boycott actions, the expressive and instrumental functions, and the positive and negative qualities of consumer boycotts. For the target of a boycott, there may be significant costs stemming from a loss of revenue or damage to their public image, logo, or reputation. For the consumer, the decision to boycott may signify a form of consumer-based political power once found in the public sphere and electoral politics.

Food Citizenship

Food justice; Food policy; Food politics; Food rights; Food sovereignty

Introduction

Food citizenship refers to individuals and their relationship to the food system insofar as they are members of a larger, political community. As food citizens, individuals are said to possess certain rights and have certain responsibilities in regard to food and the food system. Many of the scholarly treatments of food citizenship are inspired by the notion that has been recently put forth in environmental studies of “environmental” or “ecological citizenship,” where the individual citizen takes it upon themselves to act in

environmentally responsible ways (Bell 2005; Dobson 2006; Latta 2007; Seyfang 2006). These discussions of food and environmental citizenship have themselves followed in the wake of renewed interest in the idea of citizenship in ethical and political theory proper (Cohen 1999; Kymlicka 2002; Kymlicka and Norman 1994). These theoretical analyses of citizenship generally treat citizenship in one of two ways, the liberal view of “citizenship as legal status” and the republican view of “citizenship-as-desirable-activity,” or what Benjamin Constant describes as the “modern” and “ancient” views of citizenship (Kymlicka and Norman 1994; Constant 1988). In the “modern” liberal view, citizens are primarily construed as legal persons or the bearers of certain rights against the state, while in the “ancient” republican model, citizens are described as political actors having certain fundamental responsibilities and duties in regard to the state. Discussions of food citizenship can generally be divided along these same theoretical lines. Some advocates of food citizenship focus primarily on the food citizen as the bearer of certain individual rights (Beekman 2008; Del Savio and Schmietow 2013; De Tavernier 2012). Other theorists, however, stress the duties and responsibilities of the food citizen in regard to the food system and the broader political community (Baker 2004; Booth and Coveney 2015; Welsh and MacRae 1998; Wilkins 2005). Proponents of this second sense of food citizenship often make a contrast between the food citizen and the food consumer (Wilkins 2005; Booth and Coveney 2015; Welsh and MacRae 1998). While the latter is seen as a purely passive consumer or eater of food, the former is taken to be more directly or actively engaged in the political dimensions of food and the food system.

The Food Citizen as the Bearer of Rights

Discussions of food citizens as bearers of rights build upon the model of citizenship that prevails in modern liberal democratic views of the nation-state, what is sometimes described as the “juridical” model of citizenship and is said to be derived

from Roman law (Cohen 1999; for a classic statement of this position, see Marshall 1950). According to this liberal democratic view, the citizen-members of a political community are viewed as moral equals and autonomous individuals, free to pursue their private or personal views of the good (provided that they don’t interfere with other citizens’ pursuit of the good). Allowing citizens to pursue their view of the good requires that we recognize that they possess certain fundamental rights or freedoms, for example, the freedom to own property, freedom of expression, freedom of religion, freedom of association, etc. (note that on the traditional liberal view, these rights are construed as “negative rights” or freedom from external influence or coercion as opposed to “positive rights” or entitlements). On this view of citizenship, then, one of the primary roles or duties of the state is to protect these rights, providing individual citizens the liberty and security they require to pursue their view of the good.

Some theorists use this liberal view of citizenship to develop a theory of food citizenship, where the food citizen is principally understood as the bearer of certain rights that pertain specifically to their consumption of food and their relationship to the food system. This notion of the food citizen is then applied to certain ongoing debates (Beekman 2008; Del Savio and Schmietow 2013; De Tavernier 2012). For example, insofar as food citizens are said to have a right to safe food, then the state and food producers are said to have a corresponding duty to ensure that food products on the market are safe or make an effort to minimize known health risks. This line of argument can be used to justify regulatory regimes (inspection systems, quality control standards, etc.) wherein the state has an obligation to ensure the relative safety of the food supply. Similarly, appeals to the right to religious freedom could be used to justify the requirement that food products be appropriately labeled (e.g., kosher and halal foods), and appeals to the right to health can be used to justify various forms of labeling: ingredients, nutritional information, the presence of potential allergens, etc.

While food safety regulations and nutritional labels aren’t that controversial, some theorists

appeal to the liberal conception of food citizenship and its concomitant set of rights to respond to more contentious issues and debates, especially in regard to food labeling (Beekman 2008; Del Savio and Schmietow 2013; De Tavernier 2012). Using the liberal notion of the food citizen, these theorists try to justify more stringent labeling requirements, in particular, labels that contain information regarding “ethical” aspects of food products and their production process, what is sometimes referred to as “ethical traceability” (e.g., the conditions under which animals are raised, labor conditions, the use of genetically modified ingredients, environmental footprints, LCAs, etc.) (Coff et al. 2007). Following the basic contours of classical liberal thought, they argue that while food citizens do not have a positive right or are not entitled to be provided with food that fulfills these values, they do have a negative right not to be misinformed about such morally relevant characteristics regarding the food they choose to purchase and eat. Access to such information (and the corresponding duty on the part of the state and producers to provide it) is, they argue, based on certain fundamental rights, be it individual autonomy (the ability to make informed and free decisions) (De Tavernier 2012) or moral integrity (the ability to uphold certain moral standards and beliefs), etc. (Del Savio and Schmietow 2013).

The Food Citizen as the Bearer of Responsibilities

Critics of the liberal view of citizenship often contend that the conception of citizenship that it puts forth implies a certain “passivity” when it comes to citizenship as citizens are said to possess certain rights but are under no obligation to directly participate in or contribute to public life. Such passivity, they maintain, leads to a privatization or atomization of existence, undermining individuals’ identification and solidarity with the larger community or group to which they belong, culminating in phenomena such as political indifference, voter apathy, etc. (Kymlicka 2002; Walzer 1989). In contrast, then, with the “legal”

or “juridical” view of citizenship prevalent in liberal political theory, defenders of civic republican conceptions of citizenship view citizenship in more overtly “political” terms, arguing that citizenship requires “active and constant participation in collective power” (Constant 1988). Beyond their possession of rights, republican citizens are defined by their direct involvement in political life and civic affairs, performing public service, voicing their opinions in the public square, participating in political debates and dialogue, etc. This republican view of citizenship can be seen in the work of figures like Rousseau but can also be traced back to Aristotle who defines citizenship “by no other thing so much as by sharing in decision and office,” that is, “the capacity to rule and be ruled” (Aristotle 1984; Walzer 1989).

Inspired by this republican notion of citizenship, some proponents of food citizenship will thus argue that the central task of the food citizen is to actively engage in ways that support the development of democratic and economically just food systems (Baker 2004; Booth and Coveney 2015; Welsh and MacRae 1998; Wilkins 2005). A central theme in much of this discussion is the contrast between the passivity of the food consumer in the face of the industrial food system where given individuals have little to no control over the decision-making process and negligible relationships with the other actors involved and the direct engagement of food citizens who, acting in concert with others, can work to remake and gain some measure of control over their food system.

Such civic engagement or activity, defenders of food citizenship argue, can take on various forms: home cooking, backyard gardening, community supported agriculture, shopping at farmers markets, forming consumer cooperatives, etc. (Booth and Coveney 2015; Wilkins 2005). The localized nature of these endeavors allows individuals to develop robust relationships with other individuals who may be involved, and their small scale makes it possible for them to exert some sort of control over any decisions that are made.

Along these lines, some theorists have explored how urban community gardens can

operate as a site for such republican food citizenship (Baker 2004). In Toronto, Canada, for example, there are around 100 community gardens scattered throughout the city, and many of the gardeners involved in these projects come from immigrant communities. Participating in these gardens offers these individuals a chance to pursue their hobby, grow culturally appropriate food, etc., but more significantly, it provides them an opportunity to break from the dominant, industrial food system and connect with each other and other stakeholders in the community, drawing them into broader social and political debates occurring in the city (Baker 2004).

Another illustration of such republican food citizenship in practice would be food policy councils or food commissions (Welsh and MacRae 1998). Such councils have been established in Knoxville, Tennessee, London, England, and Toronto, Canada. The immediate aim of such councils is to address concerns regarding food justice and food insecurity. However, by bringing together various stakeholders in the local community, private citizens, government officials, health professionals, community activists, regional farmers, etc., they provide a forum wherein individuals can act as food citizens in the republican sense, actively working to shape and transform local food policy. Thus, rather than treating people in local communities who are hungry or food insecure as mere consumers and simply working to help them gain better access to the market, food policy councils seek to address problems by forging responses on the level of public policy.

Criticisms

The notion of food citizenship, in both its liberal and republican iterations, is fairly recent, and so critical literature aimed at the concept is, at this point, scant. As noted above, the theory of liberal citizenship itself is often criticized by defenders of the republican view for being passive and apolitical, and the same argument can thus be made in regard to liberal conceptions of food citizenship.

Similarly, the republican view of food citizenship is itself susceptible to the criticisms that are frequently offered of republican citizenship in general. One such criticism of republicanism is that it can result in or be founded upon a certain level of exclusivity wherein participation in political deliberations is restricted to a select few on the basis of economic status, gender, ethnic identity, etc. (Kymlicka 2002). Along these lines, some thinkers have argued that the localized practice of food citizenship falls prey to similar problems as such groups, while promoting participation internally, can exclude certain marginalized groups (Lockie 2009; DuPuis and Goodman 2005).

Another set of criticisms is more practical in nature, as some thinkers argue that the kind of active political participation championed in republicanism is really only possible in small communities where individual citizens can have some sort of assurance that their views will be heard and that their decisions will make a real difference (Kymlicka 2002). As such, the republican strand of food citizenship is really only feasible on a localized, small scale, and claims about how such citizenship can transform the global food system at large are thus called into question.

Conclusion

Following the lead set by discussions of citizenship in political theory, conceptions of food citizenship generally conceive of food citizens in either liberal terms as the bearers of certain rights or in republican terms as active participants in their local food communities. While proponents of these respective views of food citizenship use them to address certain debates and issues that arise in regards to the food system and food politics, these conceptions of food citizenship are themselves subject to the same criticisms aimed at their theoretical forerunners, liberalism and republicanism. One can easily imagine, however, that as debates in political theory regarding citizenship evolve or as new conceptions of the citizen emerge that these may have an effect on future discussions and conceptions of the food citizen.

Food Cooperatives in Canada

Simon Berge and Masud Khawaja
Business and Administration Department,
University of Winnipeg, Winnipeg, MB, Canada

Synonyms

[Capital](#); [Commons](#); [Community](#); [Co-operatives](#); [Democracy](#)

Introduction

Food has played a key role in the development of the cooperative model. From the initial offering by the Rochdale Equitable Pioneers of butter, sugar, flour, and oatmeal, cooperatives have provided access to food for those with limited means (Holyoake 1893). Cooperatives have addressed issues of access by involving the community in the development of firms that address basic needs such as food. This discussion will look at the development of cooperatives as these firms address a community's basic need for food by applying the cooperative principles. The development of cooperatives and their guiding principles

represent an ethical response to perceived injustices within the economic system.

This entry will look into the ethical question that revolves around the focus on capital within the investor-owned firm (IOF) and the focus on the member within the cooperative firm. The capital focus of an IOF drives the firm to look inward for efficiencies to produce higher returns on the capital investment for shareholders. When a firm focuses on members, there is a view outward to what a membership community requires of the firm.

As a response to the lack of focus on community needs, the cooperative model incorporated the democratic member control principle as a means of empowering the community through individual democratic participation. The democratic member control principle ensures that each member of the cooperative, regardless of their financial state, is provided with a vote within the firm. The one member, one vote democratic principle is one of the key tenants of the cooperative business model. This democratic cooperative principle changes the focus of a firm from a focus on capital needs to community members' needs. This change of focus from capital to the individual calls into question the basic tenets of human nature within an economic system.

The neoliberal capitalist belief about human nature is that the individual is self-focused and hyperrational. However, this overarching belief about the individual should be reexamined in light of the work by authors such as Elinor Ostrom (2000) and her seminal work on resource management. Ostrom's (2000) work shows that communities can utilize common pool resources without the resource falling into disaster as outlined in the tragedy of the commons. The tragedy of the commons refers to the inability of a group to manage a common resource due to each individual's tendency to overuse the resource for self-benefit. Overuse of the resource creates problems, often destroying its sustainability. Self-limitation of the use of the resource, however, is not effective if your neighbors do not also refrain from overuse. The resource, it is believed, eventually collapses due to community overuse, and the individual will have lost any short-term benefits of taking their

share prior to the collapse of the resource (Hardin 1968). Ostrom's (2000) work has shown that the tragedy of the commons is not a predetermined outcome of collective resource management. Human nature has not shown that resources are overused due to each individual focusing on their own short-term wants as communities have been able to manage resources sustainably as a collective or cooperative (Ostrom 2000).

The capitalist system encourages consolidation, slower growth, importance of inheritance, and excess use of resources in a manner that could produce an outcome similar to the tragedy of the commons. Individual firms act in a self-interested way to utilize basic resources, for the interest of the firm and its shareholders, due to the competitive nature of the economic environment. As IOFs focus inwardly to ensure their own survival and the return on investment expected by their shareholders, less focus is put toward outward sustainable resource development to address the needs of the broader community. By failing to address the broader community needs, the capitalist system produces market failures.

The cooperative firm has traditionally developed in response to market failures (Fairbairn et al. 2000). These market failures leave communities with limited access to necessary resources such as food creating food deserts. Food deserts are urban neighborhoods and rural towns without ready access to fresh, healthy, and affordable food. Alkon and Norgaard (2009) found a direct correlation between lack of healthy, affordable food choices and the incidence of diet-related diseases, such as obesity and diabetes, which disproportionately affects the low-income population. The term food swamp may be more appropriate than food desert for areas where food of poor nutrition is available. The most critical issue in North American urban settings is not insufficient access to food calories but rather the easy availability of unhealthy, energy-dense snack foods through corner stores in low-income neighborhoods.

In response to the decreased access, communities band together to create a food cooperative that will service their community's needs. This community development of a cooperative firm to

provide access to products and services has been going on for over a century. The Rochdale Equitable Pioneers of Manchester, England, were the first to formalize a method for ethical business practices that addresses their community's needs.

From Rochdale to Canada

This section will provide the historical background on cooperative development from the original Rochdale Society of Equitable Pioneers including cooperative development in Canada by the Desjardins as influenced by Friedrich Wilhelm Raiffeisen. This section will present the ethical beliefs that drove these original cooperative pioneers to develop a cooperative business in response to perceived injustices within the economic system of the time. The historical context will show that the Rochdale Pioneers established their businesses out of an ethical concern for the community's access to basic products such as food. The cooperative model was then moved from a response to the need for a basic necessity to a means of empowerment within the economic system by providing access to credit via the Caisse Populaire established by Alphones and Dorimène Desjardins of the Province of Quebec.

While the beginnings of cooperation are a highly debated topic, it is generally agreed that the Rochdale Society of Equitable Pioneers, normally referred to as the Rochdale Pioneers, formalized the cooperative principles that form the basis for modern-day principles. It was on December 21, 1844, that a group of 28 weavers joined together to form the Rochdale Society of Equitable Pioneers as a retail enterprise. Each weaver invested 1£ to start the cooperative business to sell basic necessities to their community such as flour, butter, oatmeal, and, to begin with, two candles. By establishing the cooperative, the Rochdale Pioneers did not just hope to sell basic goods but provide employment for their members who were out of work or poorly paid. The cooperative even went so far so to seek to provide housing for their membership (Holyoake 1893). *The economic interactions that take place at food cooperatives are combined with social interactions which help*

foster relationships between community members. These make such alternative food systems valuable community institutions.

The idea that a business would seek to provide services over and above the basic product line which it sells would seem counterintuitive to today's approach to economic activity. The Rochdale Pioneers developed their cooperative with an outward-facing focus in order to address their members' needs. Each member not only provided the necessary investment to establish the cooperative firm, but the democratic principle allowed the membership to define the members' needs, which drove the firms' activities.

The Rochdale Pioneers formalize the relationship of the firm to the membership by establishing guiding principles for all business activities conducted by the firm including democratic rights of the membership. The Rochdale Pioneers originally outlined 12 guiding principles, but in 1995, the International Co-operative Alliance (ICA) held a conference in Manchester, England, to update the original Rochdale principles. The outcome from the Manchester conference was a list of seven principles that are meant to guide cooperative business practices. The seven principles are:

1. Voluntary and Open Membership

Cooperatives are voluntary organizations open to all persons able to use their services and willing to accept the responsibilities of membership, without gender, social, racial, political, or religious discrimination.

2. Democratic Member Control

Cooperatives are democratic organizations controlled by their members, who actively participate in setting their policies and making decisions. Men and women serving as elected representatives are accountable to the membership. In primary cooperatives, members have equal voting rights (one member, one vote), and cooperatives at other levels are also organized in a democratic manner.

3. Member Economic Participation

Members contribute equitably to, and democratically control, the capital of their cooperative. At least part of that capital is usually the

common property of the cooperative. Members usually receive limited compensation, if any, on capital subscribed as a condition of membership. Members allocate surpluses for any or all of the following purposes: developing their cooperative, possibly by setting up reserves, part of which at least would be indivisible, benefiting members in proportion to their transactions with the cooperative, and supporting other activities approved by the membership.

4. **Autonomy and Independence**

Cooperatives are autonomous, self-help organizations controlled by their members. If they enter into agreements with other organizations, including governments, or raise capital from external sources, they do so on terms that ensure democratic control by their members and maintain their cooperative autonomy.

5. **Education, Training, and Information**

Cooperatives provide education and training for their members, elected representatives, managers, and employees, so they can contribute effectively to the development of their cooperatives. They inform the general public – particularly young people and opinion leaders – about the nature and benefits of cooperation.

6. **Cooperation Among Cooperatives**

Cooperatives serve their members most effectively and strengthen the cooperative movement by working together through local, national, regional, and international structures.

7. **Concern for Community**

Cooperatives work for the sustainable development of their communities through policies approved by their members (ICA 1995).

The guiding principles outlined above are meant to assist cooperatives in enacting their values within their business practices. Many of the principles are outward facing from the firm such as education, training and information, cooperation among cooperatives, and concern for community. These cooperative principles look to extend business practices beyond the efficient production of goods and services to include development of the members and community in which

the cooperative resides. Such concern for community can be seen in the development of the cooperative movement in Canada as the Desjardins of the Province of Quebec established their cooperatives in response to high interest rates endured by rural farmers at the time.

Canadian Cooperative Development

The history of cooperatives in Canada begins with the Desjardins through the Caisse Populaire in Quebec on December 6, 1900 (Fairbairn et al. 2000). The original cooperatives utilized a credit union business model to help farmers gain access to credit and avoid usury fees from the standard banking models of the time. The high interest rates charged by the banks of the time depressed the rural economy which was strongly agrarian, making the lives of rural farmers exceedingly difficult.

The Desjardins took their inspiration from Friedrich Wilhelm Raiffeisen's concepts of rural community cooperation. Raiffeisen, a village mayor in Germany, was the founder of the first rural cooperative with a vision to build a cooperative movement based on education and leadership (Fairbairn et al. 2000). Raiffeisen believed that:

The balance has been upset; rural areas and smaller trades have been left behind. It lies to them (neighbours) to take possession of the benefits of the new age; then, they won't wish any more to have the good old days come back. (Raiffeisen, 1866 as quoted in Fairbairn et al. 2000, p. 20)

From this statement, it is possible to see that Raiffeisen believed that a rebalancing of economic power was needed. The existing system put power into the hands of larger enterprises leaving the working class and smaller business behind. Raiffeisen saw the power imbalance within the economic system of the time as an ethical issue, which needed to be addressed. The development of an economic model that encourages cooperation and would empower smaller businesses and communities was seen as a solution to the consolidation of power within the system.

Seeing a similar separation between the larger firms and the small rural land holders, the Desjardins took their inspiration for cooperative development from Raiffeisen. The Desjardins sought to develop a similar cooperative model in order to shift the economic power toward small rural farmers. The Desjardins saw the threat of economic disempowerment as similar to the threat of democratic freedoms:

Instead of being governed like peoples were two or three centuries ago, by an autocratic king who presented himself as an emissary of heaven, we govern ourselves and we regulate everything connected with the political world by the agency of our freely elected deputies. Why should we not have an equally free regime in the economic world? (Desjardins 1907 quoted in Fairbairn et al. 2000, p. 20)

The Desjardins were expressing the concept that only through equality of economic power, just like political power, can consumers participate in their communities and thus in their community development. Desjardins believed that the firm must look past its own needs and see to the needs of the community in which it serves in order to be sustainable (MacPherson 1979).

The Desjardins and Raiffeisen put their mark on the cooperative movement in Canada, emphasizing education, leadership, and democracy as key components of the cooperative firm. As the cooperative movement continued into the twenty-first century, the participatory, democratic principle remains key to the business structure. The one member, one vote principle of the cooperative is the corner stone of the cooperative, representing the participation of members in the economic development of their business and by extension their communities.

The original cooperatives began as credit unions to address access to capital issues faced by rural farmers and the working classes. The establishment of high interest rates by the banking system at the time proved to be an ethical concern that the Desjardins could not ignore. The cooperative model continues to address empowerment issues within the banking system, but it has also extended its influence into housing, healthcare, agricultural boards, and other sectors. The cooperative model has extended into additional sectors

of the economy in order to address the needs of those people who have limited access to society's services. This does not mean that cooperatives offer free services to those who do not have the means. Cooperatives were meant to provide services for fair prices to meet a community's need in a sustainable manner.

It was the issue of fair prices that initiated the development of cooperative on the Canadian prairies. The agrarian-focused cooperative movement of the prairies that began just prior to the twentieth century focused on the inclusion of democratic participation in the economy very much like the Desjardins' Caisse Populaire. Inclusion of democracy in economic activities was a reaction to regional underdevelopment on the prairies. Prairie farmers had been locked in to a monoculture, staple production system that squeezed grain producer's to the point of subsistence living. Agricultural marketing agencies, farm supply cooperatives, and eventually the wheat pools would offer more economically democratic alternatives to the conventional market system that was characterized by unequal exchange (MacPherson 1979). Cooperatives on the Canadian prairies much like the Caisse Populaire in Quebec sought to address an empowerment issue within the economic system through collective, democratic economic activities.

George Keen, one of the leading builders of the cooperative movement, visited the Canadian prairies regularly during 1922 and 1939. Keen believed that all human beings have a fundamental interest in the preparation, manufacture, and distribution of high-quality consumer goods sold at fair prices. Keen's consumer theory of cooperation de-emphasized the overproduction of goods through economies of scale which Keen believed brought about inflated prices, conspicuous consumption, misleading advertising, exploitative practices, and class warfare. Controlling the resources of a community through a democratic, cooperative model would avoid these issues refocusing production on community needs (Keen 1950).

Keen's view of cooperatives was that they were to focus on fair prices, appropriate consumption, avoidance of consumer manipulation

through poor advertising, and effective allocation resources. Cooperatives could also bring the elite and working classes together for mutual benefit via community development. Keen's views on democratic allocation of resources came from the overarching Rochdale Principles defined between 1844 and 1854. Keen (1950) believed that if cooperatives help community economic development through democratic participation, then the development of social injustice through inequality of economic power would be alleviated. Furthermore, from a divine command ethical theory perspective, about 30 years ago in their 1986 pastoral letter, *Economic Justice for All*, the US bishops emphasized the concept of justice as participation of all members of society in service of the common good. Such cooperative economic practice exemplified justice through participation (Pfeil 2012). This basic theological concept serves to ground cooperative economic practices in communities.

Empowerment

According to Gomez and Helmsing (2008), local commercial activities, which include currency systems, can affect the quality of communities through empowerment via greater economic opportunities. The democratic principle of one member, one vote embedded within the cooperative business model provides a means to enact community participation within the economic system. Community members have the opportunity to become more than just consumers within the food system through their active participation in the cooperative firm.

In addition to the democratic principle espoused by the cooperative model, the education, training, and information principle also assists community members in participating in the economic system. McGregor (2005) argues that consumer education helps people develop inner power and social potential to challenge the status quo. This consumer education according to McGregor (2005) cannot be unlearned and creates a form of sustainable consumer empowerment. McGregor believes that enabling consumers to

do something through skills development alone does not empower them as long as they believe they have no authority to take action, i.e., an inner perception of power. McGregor (2005, p. 440) sees empowerment as increasing the political, economic, and social strength of individuals and groups that have been marginalized or excluded from the main power structure in a society (including the marketplace and civil society in a consumer culture).

Consolidation within the Canadian food system has disempowered and disconnected consumers from the food system (Fresco 2009). Cooperatives have sought to redress the lack of consumer empowerment through a combination of educational programs and democratic participation for their members. This focus on empowerment harkens back to the origins of the cooperative model and the Rochdale Pioneers as well as the Desjardins. Both the Rochdale Pioneers and the Desjardins sought to provide opportunities for their community members to act within the economic system for the benefit of their communities.

Allen's (1999) concept of community food security (CFS) provides an understanding of how entire communities have become disempowered by the food system and what actions are needed to address the disempowerment. By relinking production and consumption, it is possible to address the irony of food production abundance within food insecure communities. Allen seeks to address this problem in which the current food production system is able to produce vast quantities of product, but excludes those who lack the financial means. The inability of individuals within a community to access food brings to light the issue of food security.

Food security is the availability at all times of adequate world food supplies of basic foodstuffs to sustain a steady expansion of food consumption and to offset fluctuations in production and prices. Allen (1999) would argue that the current food system is disconnected from the consumer, leaving individuals and communities food insecure. The organization of the current food system raises the issues of empowerment or ownership of the system itself, which leads us to discuss food sovereignty.

Food sovereignty is the right of each nation to maintain and develop its own capacity to produce its basic foods respecting cultural and productive diversity. La Via Campesina brought this definition of food sovereignty forward in response to the disempowerment of local farmers. La Via Campesina is a movement of farm workers, peasant, farm, and indigenous peoples' organizations from multiple regions from around the world. La Via Campesina is very much like the cooperative movement, which seeks to provide a voice in the management of the food system through the democratic principle. It is only through the development of a means to exert influence over a system that an individual or community is truly sovereign over the system (La Via Campesina 1996).

Foucault (1979, p. 136) outlined the change in sovereignty from the "right to kill" to the ability to "seize, manage and exert influence over the living conditions of individual bodies and whole populations." Cooperatives provide a means for individuals and communities to participate within the food system, through the cooperative principles, which allows communities to exert influence over the system for the benefit of the community. This was evident on a mass scale in terms of the women empowerment achieved through disbursement of agricultural microcredits by the Grameen bank, an initiative of Nobel Laureate Muhammad Yunus (Boyatzis and Khawaja 2014).

Conclusion

Cooperatives within the Canadian food system offer communities the ability to act within the system in a manner that is over and above simple consumerism. While our discussion focused on the democratic principle of one member, one vote as a means of empowering communities, the guiding cooperative principles provide an understanding of economic activity beyond a simple return on investment. The focus on capital as the driving force behind the development of the food system diminishes what should be the very purpose of the system, i.e., the development of food security and sovereignty for communities.

Introduction

The public's fascination with chefs can be tracked through the rising celebrity of chefs like Jamie Oliver, Gordon Ramsay, and Heston Blumenthal. No longer confined to the kitchen, chefs with prominent media presence have created a changed role for professional chefs which can require skills other than cooking in order to be successful. Appearing on cooking programs, writing

cookbooks, and promoting household products are just some of the additional jobs required of chefs in order to maintain a profile and run a successful business. Chefs themselves have become brands, changing perceptions of the hospitality industry significantly. This entry gives an overview of celebrity chef culture and some of its effects. In order to understand the celebrity chef phenomenon, this section examines celebrity culture, food criticism, and the increasing influence of social media.

Celebrity Culture

The perception of cheffing is changing. One of the key factors of this change is the incorporation of celebrity culture into the restaurant industry. To reach a level of success that transcends working in the kitchen, chefs have become media savvy and authoritative and appear approachable. The plethora of media channels through which chefs can reach their audience includes television cooking programs and online social networking sites like Twitter and the photo-sharing platform, Instagram. The combination of these media sites, in addition to the authority and taste standards constructed by food critics for chefs and diners, can build the chef as a figure of celebrity.

Celebrity culture is a field that is conceded to be ambiguous, and the definition of “celebrity” is constantly evolving (Marshall 1997; Turner 2004). P.D. Marshall describes celebrities as “overtly public individuals” (1997, p. ix). These individuals, he argues, are “given greater presence and a wider scope of activity and agency” (1997, p. ix). Graeme Turner adds, “What constitutes celebrity in one domain may be quite different in another” (2004, p. 17); certainly the celebrity chef is only a ‘celebrity’ in certain contexts. Both Turner and Marshall agree that contemporary celebrity is the result of “a significant shift in popular culture” (Turner 2004, p. 6) and that it “constitutes a change in the way cultural meanings are generated as the celebrity becomes a key site of media attention and personal aspiration, as well as one of the key places where cultural meanings are negotiated and organised” (Marshall

1997, pp. 72–73). There are many chefs who fit these definitions. Jamie Oliver and Gordon Ramsay, for instance, are perhaps the most recognizable contemporary celebrity chefs globally. Both communicate certain values of food, particularly in the case of Jamie Oliver, who promotes healthy cooking and eating through his Ministry of Food project.

With celebrity chefs acting as “ambassadors” of the restaurant industry and sharing their knowledge of food, the public can benefit from the social function of celebrity. As Turner, Marshall, and Bonner argue, “the individual celebrity persona provides a powerful condensation of meaning which can be attached to commodities and issues; similarly, celebrities can act as prisms through which social complexity is brought back to the human level” (2000, p. 66). Contributions of knowledge and opinion from chefs (as judges on cooking shows) position them within the realm of celebrity culture.

Celebrity chefs can be understood through the sociological understanding of celebrity. Marshall considers celebrity as a site of power (1997, p. ix) and as a position that “celebrates the potential of the individual” (1997, p. 43). Marshall defines the “celebrity function” as having the capacity to “organize the legitimate and illegitimate domains of the personal and individual within the social” (1997, p. 57). This organization of domains occurs especially on cooking programs in which audiences are shown a specific way to cook or eat. Television is the primary domain for celebrity chefs; the particular celebrity constructed on television is of a more intimate nature, relying on “an aura more of familiarity than one modalized around distance” (Marshall 1997, p. 122). Celebrity chefs on cooking programs present their skills as specialized and professional. Tania Lewis considers the importance of “celebrity intellectuals” in light of the “shifting nature of the relationship between contemporary intellectuals and the mediatized public sphere” (2001, p. 234). With social media giving users more power (Rosen 2006, 2010; Lewis 2010), the figure of the public intellectual has evolved to include what Lewis describes as the “more pragmatic figure of the celebrity intellectual” (2001, p. 235).

Lewis argues that celebrity intellectuals may be “more useful for thinking through the changing status of the intellectual in a postmodern public sphere” (2001, p. 235). Increasingly, the knowledges and authority of chefs see them moving toward being placed under the category of “intellectual.” Chefs’ popularity also contributes to what Lewis describes as “a model of intellectual practice that foregrounds rather than disavows the dialectic of *elitism* versus democratisation that inevitably underpins the status of the intellectual” (2001, p. 236, original emphasis). Chefs position themselves as sharing knowledge with everyday audiences; they emphasize the importance of good food for families and people with busy lifestyles, serving what Gramsci calls the “social function” of an intellectual (Gramsci 1983, cited in Lewis 2001, p. 237). Another way to consider celebrity chefs is as “lifestyle experts” (Lewis 2010). Celebrity is increasingly attached to personalities who share ideas and suggestions for different lifestyle subjects such as home decorating as well as cooking (e.g., Martha Stewart). As such, celebrity chefs fall under this category of “lifestyle expert.” As a result, chefs have the choice to be associated with particular ideas or products, enabling them to promote their own celebrity profile at the same time. While media exposure can contribute in large part to a chef’s celebrity status, celebrity “power” “becomes activated only through cultural “investment” in the construction of the celebrity sign” (Marshall 1997, p. 57). This cultural investment comes from food criticism, which lends cultural authority and legitimacy to the work of celebrity chefs.

Food critics are vital to the production of celebrity chefs, creating a discourse through which the industry – and chefs – can be understood. Turner comments, “The more important development, in my view, is the scale upon which the media have begun to produce celebrity *on their own*” (Turner 2010, p. 15, original emphasis). This production of celebrity can be seen in media texts such as *MasterChef*, *Jamie’s 30-Minute Meals*, or *Heston’s Feasts* and the influential San Pellegrino 2012 World’s 50 Best Restaurants (San Pellegrino 2012; covered in more detail in the next section). Popular media gives chefs a mainstream platform

to share their work, while the World's 50 Best legitimises chefs work through critical appraisal. The more critical acclaim a chef receives, the more opportunities and access to media he or she will have.

Marshall argues that celebrities can be used to "make sense" of the world around us (1997, p. 51). Celebrities are produced by the cultural industry and are figures of cultural legitimation. To consider chefs in the context of celebrity culture is to consider celebrity chefs as legitimising figures of dining out and cooking as a cultural pursuit.

Food Criticism

Print media have shaped the culture of dining and continue to interact with new media discourses on fine dining. Internationally, star ratings in the *Michelin Restaurant Guides* are highly regarded. Along with *Michelin*, critical acclaim in the San Pellegrino World's 50 Best Restaurants list (published in *Restaurant* magazine) is highly coveted by chefs. Food critics provide potential diners with ideas of what to expect and in doing so shape the ways in which the industry evolves.

A text like the *Michelin Guide* or World's 50 Best can be read in the context of cultural criticism as an example of Bourdieu's concept of cultural capital (1984, p. xvi). Bourdieu's idea of cultural capital is a useful resource with which to analyze the effects of food criticism both on chefs' working lives and on media and patrons' consumption of chefs. Bourdieu states, "A work of art has meaning and interest only for someone who possesses the cultural competence, that is, the code, into which it is encoded" (Bourdieu 1984, p. xxv). The media produce chefs as authority figures on the assumption that its audience has the "cultural competence" to appreciate and accept their authority. "Cultural competence" is constructed with the information provided by the publications – such as the *Guide* – about which food trends are the most popular and which chefs are the most talented. In turn, chefs' skills and knowledges translate to cultural capital in the eyes of their audiences and the media.

As Arjun Appadurai notes in his *Modernity at Large: Cultural Dimensions of Globalization*, "the modern world... is now an interactive system" (1996, p. 27). Appadurai's ideas of "neighbourhoods" (1996, p. 178; drawing on Benedict Anderson's 1991 *Imagined Communities*) and "global cultural flow" (1996, p. 178) form a framework for the idea of chefs' global community. Appadurai's notion of the globalized, delocalized world allows for a global chef community, and it is therefore necessary to consider international practices. An examination of key international food criticism texts highlights the existence of a global template of food criticism and the evaluation of the global chef community to produce a chef economy that trades on symbolic cultural capital.

Bourdieu suggests, "The pure gaze is a historical invention linked to the emergence of an autonomous field of artistic production; that is, a field capable of imposing its own norms on both the production and the consumption of [chefs'] products" (1984, p. xxvi). The food critics' gaze is a form of governance. As cultural gatekeepers, food critics impose norms – that is, standards – on chefs' work, and they assert these standards in their reviews. As Bourdieu argues, this gaze of critics and diners alike is not unbiased and pure, but loaded in terms of cultural capital in the form of potential critical approval. Bourdieu argues there is no real autonomy in artistic production but that the field is shaped by a governing gaze (p. xxvi). By giving chefs attention and accolades, food critics are simultaneously guiding audiences into having certain expectations of their dining experiences. These experiences and the food consumed become objectified cultural capital (Bourdieu 1997, p. 47).

Bourdieu argues that capital takes time to "accumulate" (1997, p. 46) and food critics build up experiences and knowledges over time that enable them to offer informed critique. "The production of social capital presupposes an unceasing effort of sociability, a continuous series of exchanges in which recognition is endlessly affirmed and reaffirmed" (Bourdieu 1997, p. 52). Bourdieu argues, "The science of taste and of cultural consumption begins with a transgression

that is in no way aesthetic: it has to abolish the sacred frontier which makes legitimate culture a separate universe, in order to discover the intelligible reasons which unite apparently incommensurable ‘choices’, such as preferences in music and food, painting and sport, literature and hairstyle” (1984, p. xxix). The creation of celebrity chefs has abolished the boundary that makes dining and food culture “a separate universe” – celebrity chefs appear on television frequently and write cookbooks that can be used by everyday home cooks. Print food media in Sydney contributes to maintaining the presence of chefs in popular discourse. Food criticism is fundamental in maintaining this presence.

Social Media

The culture of participation is a key characteristic of the chef economy; in particular, Instagram and Twitter have significantly influenced practices of consumption. Social media facilitates various participatory practices sharing photos of restaurant experiences online and tweeting about it. These practices have the capacity to reach wide audiences on social media, allowing users to connect to other users sharing mutual interests. Henry Jenkins argues contemporary media culture is less “spectatorship” and more a “participatory culture” (2006, p. 3). He explains, “This circulation of media content – across different media systems, competing media economies, and national borders – depends heavily on consumers’ active participation. I will argue here against the idea that convergence should be understood primarily as a technological process bringing together multiple media functions within the same devices. Instead, convergence represents a cultural shift as consumers are encouraged to seek out new information and make connections among dispersed media content” (2006, p. 3). Jenkins’ analysis particularly comes from observations of fan cultures and their appropriation of primary materials (2006). The participatory culture that occurs in the chef economy is similar to what Jenkins describes in his fan cultures; however, primary materials (food cooked by chefs) are

less “appropriated” than directly reproduced – as in photographs or using chefs’ cookbooks, for example. While Jenkins speaks of media consumption in general – news, entertainment, popular culture, etc. – his ideas can be extended to consider consumers of the chef economy in order to understand its particular economy of consumption. “Participatory culture” occurs when photos of food are taken at restaurants and shared on Instagram or when diners are tweeting about their meal at a restaurant. This culture is present among chefs and their diners. Participatory culture is characteristic of the chef economy; participatory culture informs consumption in the chef economy and is significant in the construction of the global chef community.

Cynara Geissler writes of the contemporary mobile phone (particularly the ubiquitous iPhone) user’s “impulse to digitally diarize is powerfully present in many (if not the majority) of our social interactions” (Geissler 2010). Geissler cites Anna Reading calling mobile phones “a wearable shareable multimedia data record of events and communication” (Reading 2009, cited in Geissler 2010). While the focus of recent research on mobile social media has been about diarizing and personal biography (Arthur 2009; Hoskins 2009; Reading 2009, as cited in Geissler 2010), sites such as Instagram and Twitter are significant in building communities in order to share common interests. Followers of chefs on Twitter and Instagram are likely to follow other chefs. Instagram also allows users to “tag” their location, providing information on the location of the photographer. Diners take photos of their restaurant food and upload these to Instagram for their friends and followers to see. The photos are a symbol of cultural capital: by posting the photo, the diner is displaying his or her involvement in the chef economy. Social media not only facilitates and encourages interaction with food culture but also provides a platform on which to signal conspicuous consumption.

With the advent of the smartphone, Geissler suggests “It is easy and intuitive – maybe even irresistible – to digitally narrate the story of our lives as they occur” (2010, online). Instagram has an intuitive interface; it is easy to fill in time

waiting in a queue or waiting for friends by simply scrolling through. The app is designed to document what might otherwise be mundane moments in everyday lives. Geissler notes that with such media, there is “the feeling that every moment is performed (for digital distribution and consumption) as much as it is lived” (2010, online). The performance of consumption is evident on Instagram. But Jenkins argues, “Each of us constructs our own personal mythology from bits and fragments of information extracted from the media flow and transformed into resources through which we make sense of our everyday lives” (2006, pp. 3–4). While Instagram allows users to document and share their everyday lives, it is also a platform on which taste is cultivated. “Taste becomes one of the important means by which social distinctions are maintained and class identities are forged” (Jenkins 1992, p. 16). Instagram contributes to the changing practices of consumption affected by the chef economy.

Chefs may have personal uses for Instagram and Twitter, but both are powerful platforms on which they can extend their profiles by documenting their everyday lives to audiences. By forming a sense of community among people who enjoy their food, chefs are able to demonstrate their authority and knowledge on a wider scale, outside of their restaurants (and away from television). This added layer of participation by the audience and chef contributes to further reinforcement of the chef as a figure of authority legitimizing food culture. As well as promoting their own work, chefs’ photos of food on Instagram can also be seen as a general promotion of good food and eating well. The social media presence of chefs adds to their authority and effectiveness with a wider audience, which makes the idea of eating well – either in restaurants or through your own cooking – a worthy idea to promote.

Chefs encourage people to think more about what they eat and have brought food quality to the forefront of dining out. But increasingly, the cultural capital possessed by chefs contributes to changing consumption practices. A key characteristic in the chef economy is its participatory nature – in consumption, in production of

information, and in the process of seeking information. Participants of the chef economy are actively seeking to identify with food culture, consequently producing a community *through* convergence culture. Thus, the chef economy controls what and how its participants consume and for what reason. The use of “new” media – that is, social media – mediates consumption of the chef economy that is in part constructed by “old” media – specifically, food criticism in print media.

Summary

Celebrity culture affects the work of contemporary chefs. It requires chefs to be active on social media and to engage with certain aspects of mainstream media. This has fundamentally changed the labor of chefs and the way their labor is understood. The cultural investment by media into chefs has produced an authoritative figure who embodies a specific kind of celebrity status: that of specialized knowledges and culinary cultural capital.

Bourdieu considers taste and distinction through the various activities people undertake in their day-to-day lives. This entry has examined significant practices of consumption and the mediated creation of a chef economy through key aspects of his work. Bourdieu’s ideas of distinction, taste, and cultural capital can be clearly seen and are clearly consumed in the chef economy through social media outlets such as Twitter and Instagram. Food critics in the print media construct cultural capital to inspire these practices of consumption in social media. The chef economy trades on cultural capital and in turn changes practices of consumption, creating a culture of spectatorship and consumption of chefs. The media creates ideas of cultural capital, and chefs scramble to embody them – in turn creating a chef economy that requires constant production and reinforcement of cultural capital to sustain itself. Engagement and consumption of cultural capital are not limited to dining at restaurants; interactions with chefs and food discourses on social media are another way of consuming and

participating in the chef economy, creating and maintaining a space in which food and chef cultures continue to flourish.

Food Democracy in Food Systems

Ludivine Petetin

Law School, University of Hull, Hull, UK

Synonyms

Alternative food systems; Democratization of the agro-food system; Local food; Sustainable food supply chain

Introduction

An increasing number of consumers are interested in food consumption and food provenance but feel relatively powerless to influence food production systems. Power in food systems is concentrated with a small number of large manufacturing and retail corporations. Agriculture and food policy and regulatory frameworks tend to be associated with neoliberal political-economic agendas.

Food democracy is a social movement which offers the public opportunities to actively

participate in how their food systems develop, allowing alternative perspectives on what food is and how food should be produced and consumed. Food democracy can be characterized as “[o]ur desire for better food, more information and choices, and preference for local action and personal involvement [which] all reflect strong democratic tendencies and a growing awareness that as citizens, our actions can help shape a more sustainable food future” (Hamilton 2011). Citizens can stimulate change. Food democracy is about empowering people to influence food provisioning, to create a more sustainable and just society where the public can actively participate in the decision-making process for foods.

By referring to examples from the United States (USA), this entry explores the principles of food democracy by first placing the concept within the food governance discourse. It further discusses the potential for food democracy to nurture “better” food provisioning through sustainability. The entry identifies the actors and key characteristics of a democratized agro-food system.

Food Control

Within food governance, two contrasting forces are present with “food control” on one side (the current food system) and “food democracy” (an alternative food system) on the other (Lang and Heasman 2004). In the “food control” discourse, food is utilized as a “vehicle of control” by big retailers and the industrial food system (Lang 2005). In contrast, food democracy is a “framework for decentralising control” (Booth and Coveney 2014).

To retain control over both the design and values of our food system, agribusiness companies especially fight the use of true and accurate labels and labeling programs. In this sense, they are anti-democratic as they proactively “limit the information and choices available to consumers, to restrict the availability of alternative products and markets, and to assure consumers there is no reason for concern about our food” (Hamilton 2004).

For some commentators, US labeling laws are “based on companies being required to provide only the minimum amount of information mandated by government” (Hamilton 2005). Companies do not reveal specific types of information which could decrease their market sales, including whether their milk is from rBST-treated (synthetic recombinant bovine somatotropin or growth hormones) cows or if their food has been genetically modified or comes from a cloned animal. Labeling limitations can restrict consumers’ right to know more about their food, such as its origin, processes, or ingredients. Voluntary labeling programs such as organic, ecolabel, fair trade, GM-free, or clone-free are authorized under specific conditions. Decisively, supporting local production could be almost impossible if legal requirements do not allow for such conditions to be revealed to consumers.

Treating food as a vehicle of control derives from the 1970s idea of utilizing “food as a weapon,” which was developed in the early 1970s by former US Secretary of Agriculture Earl Butz appointed to office under President Nixon and kept under President Ford (Wallenstein 1976). During his mandates, the USA planted “fence row to fence row” to maintain the US economic supremacy worldwide through intensive agriculture (USAID 1974). A centralized food system was established where agribusiness companies were promoted to feed the world cheaply and profitably. Under this new policy, “the enemies were hunger, poverty, ignorance, and Communists, as well as nations who did not open their markets to American exports or subject their farmers to the forces of free trade and the power of America’s farms” (Hamilton 2005). Food as a weapon is a rationale that continues the destruction of farming, rural areas in particular with the use of any new technology “even over the objections of our customers” (Hamilton 2005). The public opposition to growth hormones and modern agricultural biotechnologies, such as animal cloning and genetically modified organisms, is challenged by agribusiness. These companies want few restrictions and no mandatory labeling to retain the control and the domination they have over the food system (Goodman 2014).

Control over food information and food labeling is the critical “battleground in the debate” (Hamilton 2005). In the current food supply chain, retailers “choice-edit” the products before consumers are able to see these products; they set contracts and specifications which frame farmers’ opportunities and consumer choice (Lang 2005). It is decisive to temper food control choices and choice-edit by increasing standards in democratically accountable ways (Lang 2005). This is why food democracy aims to reveal and “challenge the antidemocratic forces of control” and pushes for more rights for citizens to participate in the decision-making process (Hassanein 2003).

A Sustainable Agro-Food System

The sustainability of food and agricultural systems is paramount. Sustainable agriculture consists in the production of food, feed, and fiber in an environmentally friendly manner to achieve food security and has been adopted by numerous states worldwide as the ultimate policy goal (European Commission, COM 2010). However, there is much debate as to how this can be achieved as it encompasses “both conflicts over values and uncertainty about outcomes” (Hassanein 2003). One pragmatic solution is to democratize the agro-food system to reflect public values, morals, and ethics.

Food democracy and sustainable agriculture are strongly intertwined. Sustainable agriculture started as a social movement with a national network and an effective policy wing which leads to food becoming political in the struggle for a just and sustainable society (Hassanein 2003). Both food democracy and sustainability discourses are broad and inclusive and encompass a broad range of individuals, organizations, and other stakeholders. Food democracy offers hope to achieve the transformation to a sustainable agro-food system that “equitably balances concerns for environmental soundness, economic viability, and social justice among all sectors of society” (Allen et al. 1991). It creates opportunities for the public to participate in their food systems

and how they develop. Food democracy has emerged to complement various alternative food perspectives and movements on what food is and how food should be produced and consumed to counterbalance the neoliberal agenda, such as sustainable agriculture, the Slow Food movement, food sovereignty, food (in)justice, and food poverty.

Food and Democracy

There are parallels between food and democracy. Food can be defined as any nutritious substance that is eaten or drunk to maintain life, provide energy, and promote growth. Critically, food is a pathway for communication and awareness (about society’s values). It is also a “tool to support farmers and companies serving the needs of consumers” (Hamilton 2005).

The term “democracy” originates from the Greek word “demos” meaning “people” and “kratos” meaning “power” or “rule.” Democracy refers to a form of government in which power is vested in the people, and every citizen has a right to vote and influence the government policies. Democracy creates decision-making processes that are more accountable to citizens and allows for public scrutiny to make the process better (Carlson and Chappell 2015). It offers the best chance for achieving environmental sustainability (Morrison 1995). A “thin democracy” is based on individualistic perspectives and rights and limits citizenship and participation (Barber 2004). This is detrimental to achieving the public good. In such a system akin to the existing agro-food system, citizens’ role is diminished and weak. In contrast, in a strong/deep democracy, citizens can unite together. Strong/deep democracy is built on engagement, active participation, and empowerment of citizens by directly involving them in the decision-making process (Prugh et al. 2000). Citizens are stronger, more organized, and unified than when isolated. Food democracy relies on this type of democracy. Such democratic processes can support and facilitate the resilience and sustainability of food systems (Carlson and Chappell 2015).

The term “food democracy” was coined in the 1990s by British food policy academic and former farmer, Professor Tim Lang (1999). Separately “food” and “democracy” may not raise more than a passing interest, but their combination into the term “food democracy” provides “insight into an expanding social movement where people can regain control of the food system” (Booth and Coveney 2014). Food is at the center of the democratic process. “The medium is food, but the theme is democracy” (Hamilton 2004). Food ought to be understood as a “locus of the democratic process” in which the interest of the mass prevails, which a bottom-up not down approach is privileged, and where social movements embed rights into culture and expectations (Lang 2005). Food is a tool to build and strengthen democracy. Both food and democracy are important to the public as citizens and as a nation; however, citizens “take each for granted” (Hamilton 2004).

Principles of Food Democracy

Food democracy’s underpinnings diverge strongly with the “highly centralized, industrial, corporate food system” that currently exists (Carlson and Chappell 2015). Food democracy suggests that all people should have access to an adequate, safe, nutritious, sustainable food supply (Booth and Coveney 2014). To this extent, it is different from food rights: it has to be “thought for and built into food culture” (Lang 2005). Food democracy goes beyond the safety of the food supply and emphasizes “decency and social justice in the food system’s wages, working conditions and internal equity” (Lang 2005). It promotes democratic values in society. Conflicts within sustainable agro-food system can be solved through active participation of the citizenry and political engagement to work out differences (Hassanein 2003). Food democracy seeks to “organize the food system so that communities can participate in the decision-making, can see the ecological risks and benefits to food system choices, and can respond collectively and accordingly” (Carlson and Chappell 2015).

It has been argued that food democracy “is not only a goal or end point, additionally it’s the processes used in achieving food democracy which are critical to our understanding of it” (Booth and Coveney 2014). It is about the values that people want in their food system. Food democracy is a “method for making choices when values come into conflict and when the consequences of decisions are uncertain” (Hassanein 2003). The question of which values should prevail over others is decisive: religion? Moral? Ethics? Values?

In an increasingly globalized world, many decisions and solutions are referred to entities at higher levels that do not have as complete a picture of the local social, political, ecological, and built environment (Carlson and Chappell 2015). Food democracy goes beyond an enhanced ability to come up with solutions. Rather it facilitates the adaptation of citizens to solutions as circumstances change. Food democracy establishes justice and fairness in the system. Citizens will agree with the outcome of a decision if that decision was adopted following a fair decision-making process because they may have participated in the decision-making process. Citizens “more readily accepts government decisions, even those with which it disagrees, when its views are accorded respect and consideration” (Du 2012). It is not necessarily about reaching consensus but about the public accepting the final outcomes.

In the USA, big agribusinesses, like Walmart and McDonald’s, evidence the shifts in food distribution, retailing, and the pressure on supermarkets to reduce prices to achieve the cheap food that people supposedly want. Interestingly, Hamilton argues that to a certain extent, these companies are “examples of Food Democracy in action” because through the reduction of prices and the increasing availability of foods, they help low-income families to spend less money on food so “they have more to spend on life’s other necessities and pleasures,” and they could provide “a positive source of information regarding health and nutrition” (Hamilton 2005). It is however unclear how and what type of information would actually be provided to buyers, in particular the provenance and nutritive characteristics of foods.

Multi-actors and Multilevels

The framework of food democracy is about reinforcing local economies, sustaining family farms, and increasing citizens' power in the food system. As such it involves numerous actors, including individuals, nongovernmental organizations, and civil society.

Food democracy is an expanding social food movement as much about “putting power back into the hands of communities, food workers, farmers and farm workers” as about “producing and distributing healthy, sustainably-grown food” (Carlson and Chappell 2015). According to Booth and Coveney, “there is a degree of control consumers can exert, for example by making individual choices about where they buy food” (Booth and Coveney 2014). How food is manufactured and commercialized is the result of an “open democratic system that not only protects freedom of speech but values the role local governments play in making decisions about land use and other public issues” (Hamilton 2005). By getting involved in local, regional, and even national food debates, citizens can transform the food supply and diversify their food sources and inputs. For example, when buying local food, consumers strengthen local food production and reduce food miles and can therefore diminish the high environmental footprint of our current food systems.

Various levels of application for food democracy can be identified at the individual, household, and community level. Food democracy operates in practice through alliances, movements, and advocacy structures to foster social change (Booth and Coveney 2014). Interactions, negotiations, and coalitions within movements, among allied movements, and between movements and their opponents create “new democratic spaces in which different social groups can learn about one another, broadening both participation and understanding” (Hassanein 2003). Food networks participate in the emergence of new types of producer-consumer relationships and cooperation (Renting et al. 2012). These various actors operating at different levels from the local to the global can “fill different niches, there are increased opportunities for citizen participation, and the

multiplicity of thought and activism creates a vibrancy that leads to new forms of innovation and new ideas” (Hassanein 2003).

In the USA, food democracy includes local and farmers' markets, community-supported agriculture (CSA) operations, food policy councils, cooperatives, urban agriculture projects, and Farm-to-School programs as well as other initiatives. For instance, the Garden School Foundation in Los Angeles provides education for underserved youth in Los Angeles through garden-based learning in outdoor living classrooms (Garden School Foundation 2015). It involves a Seed to Table curriculum and the overall garden-based education program through the use of a School Community Garden to transfer knowledge to pupils and their families about gardening and healthy cooking.

Key Characteristics

Food democracy highlights and strengthens the democratic right of citizens to choose the food they purchase and eat, foods which have been produced in an environmentally friendly and ethically sound manner but which also ensure food quality and respect social costs. It recognizes the role of stakeholders in food production and distribution, reflecting distributive justice in responding to the curiosities and worries of such stakeholders.

To establish a theoretical framework for food democracy, Hassanein proposes the following five dimensions (Hassanein 2008):

- (i) Collective action/collaboration toward food system sustainability
- (ii) Becoming knowledgeable about food and the food system
- (iii) Sharing ideas about the food system with others through discussion and deliberation to enable citizens to clarify issues and discuss values
- (iv) Developing efficacy to achieve specific outcomes with respect to food and the food system
- (v) Acquiring an orientation toward the public/community good

A democratic food system ought to fulfill certain conditions (Hamilton 2004):

- (i) Broaden the involvement and representation of all segments of the food system in decisions.
- (ii) Provide information and education.
- (iii) Promote not just a proliferation of foods, but of markets, farms, and food processors, as well as opportunities for consumer satisfaction.
- (iv) Provide room for local farms, support markets that feature a wide range of foods, and nurture an appreciation for the role food plays in culture and tradition.
- (v) Encourage citizens to want more information about their food and more food choices, farmers to want more for the futures of their children and workers on industrial farms, and individuals to want better tasting, fresher, more wholesome and more nutritious food.

Social movements like food democracy exert pressure to “democratize the dominant food system” and challenge “the forces seeking control of the system and the very structure of capital itself” (Hassanein 2003). Another decisive aspect of food democracy is to “help people understand the true costs of producing healthy, high-quality food and to give them ways to support an alternative system, then one side effect may be to increase food costs” (Hamilton 2005). This movement rejects highly processed and cheap food as the real cost of cheap food is shifted out of the market and onto society. Food democracy is a movement where citizens pay more for foods. Increased prices reflect the actual cost of foods currently borne by society as a whole through incurred costs of poor diets, obesity, environmental damage, and underpaid agricultural workers. Cheap food that citizens are supposed to want hides the true costs of farming and food production.

Food democracy is not an elitist concept but offers opportunities for consumers to find satisfaction when buying products they want while supporting the farming practices that help preserve the environment and the land (Hamilton 2005). Farmers can identify markets and opportunities and remain on the farms to care for the land

and their families to achieve freedom in the food system through local food, organic production, and the empowerment of small-holder farms and women in farming.

Overall four critical characteristics of food democracy can be identified:

- (i) True information, genuine choice, and alternative products being offered to consumers
- (ii) Upstream engagement and bottom-up approach in the decision-making process
- (iii) Good health, food safety, sustainable agriculture and environmental protection, and improvement of the rights of farmers and agricultural workers and their opportunities
- (iv) Restoration of faith and trust in the food system, its institutions, and in farmers.

Alternative food systems and agribusiness will nonetheless coexist giving consumers true choice about the food they eat (Booth and Coveney 2014). Democratized agro-food systems will include different kinds of farming and companies and models of production, distribution, and retailing.

Finally, a key democratic value is the ability to choose; the issue is to make sure that there are actual alternatives for consumers to choose from. Retailers of various sizes and local food systems will coexist offering consumer options. This is what food democracy is about: giving choices and alternatives for people with various incomes.

Summary

Food democracy is an increasing global phenomenon focusing on the people, the land, and environmental protection. It is an incremental process to remake the food system. Food democracy aims to broaden the involvement and representation of consumers in decisions relating to the food system. It turns passive consumers into active citizens by providing information and education to citizens, engaging them with food. Citizens can exert power, remodel, and improve the existing food system. Through empowerment citizens can influence food provisioning and create a more sustainable and just society where the public can actively participate in the decision-making

process for foods. New food systems based on the premises and philosophies underpinning food democracy aim to restore and ensure confidence in the food supply chain.

Food Deserts

Daniel R. Block
Chicago State University, Chicago, IL, USA

Synonyms

[Food swamp](#); [Low-food-access zone](#); [Obesogenic environments](#)

Introduction

Interest in areas with poor access to healthy foods, or what have often been dubbed “food deserts,” has greatly increased over the past 15 years in the USA and the world. Since the 1990s, when the concept of “food deserts” and their possible

connections to health was first suggested by researchers and activists in the UK, the idea that low access to supermarkets carrying a wide variety of healthy food items may lead to negative health effects has been investigated by a number of academic and nonacademic authors. In addition, working to eliminate food deserts has become a key focus area of many organizations working on urban food issues, particularly in the USA.

The term “food desert” originated in British antipoverty activism and policy. It is generally sourced to a resident of a Scottish public housing project who used it to express the experience of living in a deprived community (Cummins and Macintyre 2002). Quickly, the term became focused on the relationships between community development and health, as a number of mid- to late 1990 UK government reports focused on the relationship between food access, community development, and health. In 2003, a study in Leeds found a small improvement in vegetable intake in a low-food-access community after a supermarket opened (Wrigley et al. 2002).

Advocacy and Policy in the USA

In the USA, interest among advocacy organizations and politicians has been particularly strong. In Los Angeles, *Seeds of Change*, a food access report completed by students at the UCLA School of Urban Planning in the wake of the 1992 race-related hostilities in which many supermarkets and corner stores were looted and/or set fire to, influenced the city to promote the opening of new markets in underserved areas and inspired the founding of the national community food security movement (Ashman et al. 1993). In Chicago, a study on food deserts by Mari Gallagher, a local independent researcher, received great publicity, including a front-page story in the *Chicago Tribune*, bringing to light the lack of supermarkets and plethora of fast-food outlets in many areas of the city and showing correlations between areas of low food access, predominantly African-American regions of the city, and negative health indicators (Gallagher 2006). Gallagher later completed similar studies in Washington, DC; Birmingham, Alabama; Savannah, Georgia;

Cincinnati; Louisville; and Detroit. Through The National Center for Public Research, Gallagher also organizes “National Food Desert Awareness Month.” *The Need for Supermarkets in Philadelphia*, a 2001 study by the Food Trust, a local emergency food organization that has since become a national leader in advocacy around food deserts, brought to light vast areas of the city with little access to supermarkets and spatial correlations with patterns of income and race as well as areas of high levels of diet-related disease (The Food Trust 2001). This study led to the Pennsylvania Fresh Food Financing Program, which provides low-interest loans to supermarkets opening new stores or improving existing stores in low-food-access areas. The success of this study in influencing policy influenced the Robert Wood Johnson Foundation to fund similar studies and lobbying efforts in Illinois, Louisiana, and New York.

As interest among funders and advocacy groups in food deserts has risen, policies addressing food deserts have moved forward in the USA at local, state, and national levels. Combating food deserts has been a key domestic agenda for the Obama administration. The Fresh Food Financing Initiative, based on the similar Pennsylvania program, announced in 2010, made available more than \$400 million to promote the development and improvement of groceries in food desert communities through New Market Tax Credits and other incentives. At the city level, many cities have pursued anti-food desert programs. Postindustrial cities such as Detroit and Cleveland have promoted urban farming and community gardens as part of the redevelopment of vacant land. In 2011, new Chicago mayor Rahm Emanuel made ending food deserts 1 of 28 focus areas of his administration. Emanuel hosted a food desert summit starring Michelle Obama and bringing together corporate leaders and community organizers. Emanuel has pushed new policies to assist urban agriculture as well as open stores in areas designated to be food deserts.

Researching Food Deserts

Despite, or perhaps because of, increasing research and policy attention to food deserts,

questions about the issue have recently become more prominent, both inside and outside academia. Questions focus on the existence of food deserts, whether they actually correlate with income and race, the relationship between food deserts and health outcomes, and the morality of the term itself.

Interest in food deserts by independent researchers and policy makers in the USA and elsewhere has been spurred in particular by proposed connections between food deserts and the American “obesity epidemic,” and the further association between both food access and obesity and communities of color. An example of this is “The Grocery Gap,” a review of US studies on food access by researchers at nonprofits PolicyLink and The Food Trust. Based on these studies, the authors conclude that accessing healthy food can be a challenge for those in low-income, rural, and minority communities; “better access corresponds with healthier eating”; and “access to healthy food is associated with a lower risk for obesity” (Treuhart and Karpyn 2010). In general, food deserts have been claimed to be “obesogenic environments.” A correlation between food deserts, predominately minority communities, and negative health outcomes including obesity is seen in many US studies. However, the question of whether the relationship between food deserts, minority and low-income communities, and negative health outcomes is causal remains a topic of debate. As Caspi et al. (2012) point out, even the methods of studying this relationship are quite nascent. In general, academic studies and the commissions and legislation that often followed have often focused on mapped correlations between food access and racial and income-based inequality. While these maps and the stories they tell are extremely powerful, questions of how to deeply investigate food access abound. Methodological questions include what kinds of stores should be included, how stores should be classified, at what scale to measure access itself, and the possible role of qualitative data.

In terms of the existence of food access as well as correlations between food access and social variables such as race and income, US and non-US studies have shown very different patterns.

The majority of US studies have found negative correlations between poverty and minority status and poor food access (higher poverty rates and percentages of minorities, in particular African-Americans, correlating with lower food accessibility), in both urban and rural areas (Black and Macinko 2008). Much of the difference seen was in the type, rather than the number, of groceries serving the area. For instance, in a national survey, Powell et al. (2007) found that low-income, predominantly African-American, and predominately Hispanic US neighborhoods were much less likely to have a chain supermarket than white and higher-income neighborhoods, which were more likely to have non-chain supermarkets and smaller grocery stores. In a three-state study of selected census tracts in North Carolina, Maryland, and New York, Moore and Diez Roux (2006) found that minority and racially mixed neighborhoods had more than twice as many grocery stores, but half as many supermarkets, than predominantly white neighborhoods. On the other hand, evidence from studies completed outside the USA is mixed, with some finding little or even an inverse relationship between measures of socioeconomic status and supermarket access, with lower SES areas having better access to supermarkets (Apparicio et al. 2007), while others have shown a relatively weak positive correlation (Burns and Inglis 2007). As in the USA, patterns by store type can be quite complicated. In Glasgow, Cummins and Macintyre (2002) found that higher concentrations of retail food outlets were located in deprived districts, including both smaller, independent stores and chain supermarkets. However, the types of chain stores differed, with discount stores being more likely to be in low-income areas and high-quality stores in high-income areas.

Looking at the body of research on food deserts as a whole, cities and countries differ greatly in the relationship between minority status and socioeconomic factors and food access, with much of the difference being the type rather than the number of stores in compared communities. This is important because store type consistently predicts both food price and availability. Cummins and Macintyre (2002) found in Glasgow that cheaper prices were generally found in chain and discount

supermarkets, followed by chains, and then independents. In a rural Australian setting, Burns et al. (2004) found that a larger percentage of the “Healthy Food Access Basket” studied was available in chain stores in larger towns than in the independents that dominated smaller towns. In the Chicago area, Block and Kouba (2006) found a complex picture. Fresh meats and produce were cheaper in independent supermarkets and groceries, while packaged items were cheaper at chain supermarkets. Discount stores were by far the cheapest, but often had low availability, while chains carried almost all items surveyed. Small corner stores, of which there were many in the lower-income, African-American community surveyed, had low availability, and if fresh produce was available, it was often of unacceptable quality.

Controversy over food desert studies was highlighted in the nonacademic media by the publishing of an article by Gina Kolata in the *New York Times* in spring 2012, based on two US studies which questioned both the existence and importance of food deserts. Lee (2012) found children in a national US cohort study living in minority neighborhoods lived more closely to convenience stores and fast-food outlets, but also to supermarkets, than those in higher-income, majority communities. In addition, differences in food access were not tied to weight gain in the children. A California study (An and Sturm 2012) similarly found no connection between food access level and eating patterns. The prominence of the *Times* article, as well as an opinion piece that followed questioning policies focused on ending food deserts, led to a level of public debate that had not been previously seen. While greatly varied, public comments focused particularly on debates over individual responsibility versus ecological explanations for obesity.

For researchers, the article highlighted how differences in scale, as well as differences between study communities can result in very different conclusions. Studies specifically focused on urban areas may differ from national studies that include both rural and urban zones, in which poverty, as well as distance to the nearest store, varies greatly. The data used for stores can also vary greatly. Many studies, including the ones quoted in the *New York Times* article, use private

data vendors that are often highly inaccurate at a local level. Another example of this is a national study completed by the USDA that only mapped chain supermarkets. Contrary to many studies of particular US urban areas that also incorporate independent and local chains, in the USDA study, predominantly African-American communities were not found to have low access to supermarkets, while predominately Latino communities did (Ver Ploeg et al. 2009). In addition, the An and Sturm article further highlighted specific connections between food access levels and eating patterns are difficult to make. While some studies have found connections, qualitative studies on the subject have suggested that food desert residents who wish to procure healthy foods travel outside their neighborhoods to stores where they are available and that the choices consumers make have much to do with the kinds of stores they shop (Zenk et al. 2005). A new supermarket opening in their neighborhood may make their lives easier, but it will not necessarily change their diet. Finally, academic questioning of food deserts was furthered by the publishing of *Weighing In* by prominent geographer Julie Guthman, which questions the idea of obesogenic environments in general and food deserts in particular, focusing on the fact that most studies of the relationship between food deserts and obesity have concentrated on correlations. Guthman also questions the focus on food deserts as an excuse for alternative food projects serving low-income minority communities that she feels are often overly parental at worst, racist (Guthman 2011).

Definitional Issues

A major issue in the study and identification of food deserts is that there is no standard definition for them or even an agreement on whether there should be a standard definition. As many of the comments on the *New York Times* stated, being 2 miles away from a supermarket is very different in Manhattan than in rural Iowa. The USDA's original “Food Desert Locator” took this into account by mapping as food deserts low-income areas, defined in a number of ways, but particularly areas that had a median household income of

80% or less of the state or metropolitan area MHI, where at least 33% of the population was more than 10 miles to the nearest supermarket in rural areas or more than 1 mile to the nearest supermarket in urban areas. Its new “Food Access Research Atlas” keeps the income cutoffs but creates three different classes of low-food-access zones, including low-income areas where at least 33% of the population is more than ½ mile (urban) or 10 miles (rural) to the nearest supermarket; more than 1 mile (urban) or 20 miles (rural) to the nearest supermarket; and a third measure that takes into account the percentage of the population that has access to a car. PolicyLink and the Philadelphia-based Reinvestment Fund created a much more nuanced method that divides US census block groups by population density and then into groups within this by car availability. From this Mari Gallagher’s consulting company, which has done food access studies nationwide, uses a measure based around a ratio between mean distance to the nearest supermarket and mean distance to the nearest fast-food restaurant. Academics have developed various methodologies for measuring food access, most coming out of more general access measurement techniques that have been used for measuring access to such things as physicians and parks. At the simplest, the number of stores in a region is counted and compared to the population. A somewhat more complex method measures distance to the nearest store and factors in population density. More complex measures utilize advanced geographic analysis techniques to create “food access” surfaces that interpolate access over space. Finally, a body of research primarily within public health looks at the “health environment” inside of the store, including such things as the mix and placement of healthy and not healthy items (Glanz 2009).

A further measurement issue is that there is little agreement on what constitutes a supermarket. How large, in particular, does a store have to be classified as a supermarket? Furthermore, how should one measure size? By square footage? By annual sales? Many researchers and policy makers studying local areas utilize the number of registers, since this is something that a quick store survey can easily gather, but it, as well as the other measures, is a rough indicator of the breadth of

food offered by the store. A small store can, in some cases, be devoted to the provision of low-cost fruits and vegetables. Another issue, as mentioned above, is the dataset used for the study. In some countries such as Canada, the national database of businesses is quite accurate. In the USA, however, many researchers rely on non-government data sources. Many, particularly national, studies in the USA have utilized purchased business databases. As mentioned above, these have varying levels of accuracy and are probably in general better at general measures of food access than specific local measures. They are also quite expensive. For ease of research, some researchers have looked only at chains. Local organizations have utilized in-person surveys, Web site reviews, Yelp pages, and other methods to improve purchased datasets or to build datasets of their own. Finally, other researchers and activists have tried to study “food swamps,” areas with high access to foods of negative value, rather than low access to healthy foods.

Another difference between food desert investigations is their goals. For most academics, the goal of studying food access is to discover overall relationships between it and socioeconomic variables such as race and class, as well as health outcomes such as diabetes, coronary disease, and obesity. The focus is generally not on specifically identifying particular low-access “food desert” areas. For these researchers a simple index with a cutoff point between food deserts and not food deserts generally makes little sense since they are more interested in the overall pattern than the identification of particular food desert areas. For policy makers, the business community, and advocates, however, the identification of specific food desert areas is often the focus. They wish to know how many people live in food deserts, where the food desert areas are, where low-interest loans and other subsidies should be focused, and what impact policies addressing food deserts have had. It should be noted, however, that the USDA has changed its indicator from being called the “Food Desert Locator” to “Food Access Research Atlas” and added two additional measures. In other words, focus has been changed from locating particular food deserts to being able to research food access in a more general way.

“Food Desert” as a Controversial and Influential Term

As mentioned above, the term food desert was, at its origin, designed to communicate the experience of living in a high-poverty area. In practice, however, areas have been defined as food deserts with little discussion of what the designation means to those living in the communities themselves. The main issue may be that geographic study of food deserts is truly only a portion of a complete study of the constraints people in various types of communities encounter when provisioning themselves and their families, both for food and many other products and services. In many food access studies, particularly ones covering a large geographic area, stores are “dots on a map.” There is little information known or studied about what is actually inside the stores or how the people in the neighborhood shop. This has been addressed through market basket and food environment studies, as well as qualitative studies, including focus groups and interviews, of those living in food deserts, but the policy focus has been on food deserts as designated zones, without these more in-depth considerations.

Organizations and activists have both utilized and shunned the food desert term for their communities. On the one hand, funding from such organizations as the Robert Wood Johnson Foundation and publicly funded programs such as the Fresh Food Financing Initiative are premised on addressing food deserts and therefore make new funds available to food desert communities. In order to access these funds, proposals usually have to show that an area is part of a food desert according to an established map, which leads to situations in which groups compare various food desert maps to find ones that include their communities, as well as declaring in public meetings that the areas they serve are food deserts. On the other hand, activists, in particular African-American activists, have objected to the term “food desert” on a number of grounds. Longtime food justice activist LaDonna Redmond, for instance, in a 2013 interview with Tanya Fields in *Ebony*, states that the use of the term food desert places focus on economic development, in specific

opening a supermarket, rather than on developing the community as a whole. There is much more needed in many “food desert” communities than a supermarket. Redmond calls food desert “a marketing term” that suppresses community-led entrepreneurship. Wal-Mart made addressing Chicago’s South Side food desert a core of its marketing in overcoming widespread resistance in the city to new Wal-Mart stores. Redmond also feels that the term masks deeper issues in the food system that lead to hunger and poverty. The food desert issue is at its root about the spatial inequality of economic, specifically retail, development. The stories tied to the maps tend to go beyond this, because food desert maps in the USA often mirror maps of negative health outcomes as well as poverty and percent minority. The primary issue for Redmond and other activists is that by focusing on mapping supermarkets, the solution becomes focused on opening supermarkets rather than addressing the reasons behind such issues as concentrated poverty, obesity, and economic disinvestment.

Redmond’s issues with the term in a sense match the reasons for anti-food deserts focus on it. The full name of the Grocery Gap study done by advocates The Food Trust and PolicyLink is “The Grocery Gap: Who Has Access to Healthy Food and Why It Matters.” The study is, thus, not just about where food deserts are but also who lives there. In the USA, this is generally found to be poor, minority, and rural communities. The main focus of PolicyLink’s activism and research is on disparities in health between races and ethnicities in the USA. For the Food Trust and groups such as the Robert Wood Johnson Foundation, the focus of the work has been on addressing the obesity epidemic and health inequalities. Since low food access tends to geographically mirror obesity levels, such patterns lead to environmental explanations for and responses to obesity in these regions.

Summary

The term “food desert” has become an accepted part of the urban vocabulary and a popular area of research. The power of the term is significant. The idea that many inner city areas have low access to

supermarkets now appears in venues from Wal-Mart advertisements to rap music. The term also brings attention on the lack of economic investment in inner city and rural communities as well as provides a possible explanation for higher obesity levels among the poor and minorities. What is still under debate is whether the power of the term is matched by reality. In general, US research tends to support the existence of food deserts in both urban and rural communities and the correlation of these food deserts with areas of poverty and high-minority areas, especially predominately African-American urban communities. However, research outside the USA generally does not find this relationship. Evidence on the specific relationship to health outcomes tilts toward finding a connection, but is more mixed and may also vary by place. The study and mapping of food deserts are also affected by the lack of a standard definition. Finally, the value and implications of the term itself are under debate among food justice and food security activists. The outcomes of these debates will be interesting to watch over the coming years.

Introduction

For the majority of people who seek food assistance, food pantries and food banks are a fixed part of household food sources, even though they are called “emergency food.” The emergency food system is best characterized as a nationalized nonprofit food bank system with thousands of predominately faith-based organizations leading the distribution efforts, though multitudes of providers of emergency food remain outside that system. Even with pantry participation in the federally funded The Emergency Food Assistance Program (TEFAP) and Supplemental Nutrition Assistance Program (SNAP) programs, emergency food generally tends to be stationed outside the traditional market with its operating procedures, supply chains, and suppliers largely unregulated, understudied, and forgotten.

History

Emergency food is the overarching term for foods distributed through shelters, food banks, food pantries, soup kitchens, backpack programs, and other institution-specific programs to hungry families and individuals. Some, but not all, families and individuals who take part in the emergency food system participate in the Supplemental Nutrition Assistance Program (SNAP); Women, Infants, and Children (WIC); or other federal programs. Food banks are large warehouse operations that store and distribute food from producers, retailers, federal commodity programs, and the food industry to the food pantries, which then distribute emergency food at the local level. Food banks and pantries are the largest part of the emergency food system, though individuals and families might also participate in community gardens, eat at church dinners, and accept foods from neighbors for sustenance. Given the focus on food insecurity, food safety can remain low priority for food pantry managers; however, foodborne illness is a serious problem that affects one in six Americans each year.

While visiting a food pantry or food bank might be the result of a crisis for many of those in need, the food pantries consistently make available and provide complimentary sources of foods throughout the year. Feeding America is largest domestic hunger relief charity, providing 46.5 million people with 3.3 billion meals annually via their 200 member food banks and 60,000 food pantries (Feeding America 2014). This network relies heavily on corporate sponsorship, retail and manufacturing donations, and federal commodity programs, namely, The Emergency Food Assistance Program (TEFAP); Feeding America and its partners distribute 80 % of all TEFAP items in the country. While grocery stores and food drives play a large role worldwide, they are not the only sources of food to the food pantries and banks. The food comes from a variety of places, from individuals and grocery stores to community gardens and restaurants. Many supermarkets operate reclamation centers, which allow employees to sift through damaged goods in consideration for donation, but they also donate prepared foods

to soup and community kitchens, as well as pantries. Additionally, salvaged or gleaned foods from producers and distributors that might otherwise be thrown into the garbage are regularly donated, as are hunted game and fish via local nonprofit organizations.

The Bill Emerson Good Samaritan Food Donation Act alleviates liability concerns for the donated goods; every state has applied this federal rule of strict liability that applies to distributors of defective products when they cause injury, typically due to gross negligence, intentional misconduct, or recklessness. The Act was passed because large grocery chains were hesitant to donate expired and nearly expired foods because of liability concerns, which would have otherwise been wasted (Cohen 2006). The legislation reduced questions regarding the donor's incentive to take care. In some states, a donor is protected from criminal and civil liability, while in others the donor protection is only civil. Additionally, some states have created stringent guidelines regarding food donation, given the lack of federal government oversight. Yet, the Act does not necessarily prohibit any particular foods for donation.

Food Safety and Emergency Food

In America, the current food safety system is the result of cooperation and management from many parts of the federal and state governments, including but not limited to the US Department of Agriculture (and departments of agriculture at the state level), the Food and Drug Administration, the Department of Defense, and state health departments. President Obama has proposed a single agency to oversee food safety policy in the United States, though its creation and implementation remains uncertain. Researchers noted, "public concern about food safety is placing increasing pressure on government agencies to be more prescriptive and proactive in their regulation of the food industry" (Garcia Martinez et al. 2007, p. 299). Each state has different means and available funds for carrying out additional protective legislation.

Yet, outbreaks (when a group of people consume the same contaminated food and at least two of them contract the same illness) and recalls (when a risky product is removed from store shelves) still occur and can do so at many points in the food system. Some private retailers from small mercantile shops to large grocery chains require their own stricter safety standards for use in the global market. Grocery stores have an incentive to set additional standards for risky products like fresh fruit and vegetables, meat, and dairy products that are likelier to be contaminated and result in long-term health implications. Third-party food safety certifications can be the result of absent federal regulations, though they are also voluntarily adopted as insurance for the store and, more significantly, proof of a major shift to food-related self-governance.

Food Dating Challenges

Grocery store products that are near or past their expiration dates are regularly donated to food pantries or are heavily marked down to make them enticing to buyers. The stores can still profit and price-sensitive consumers can obtain products they might not have otherwise. Yet, these policies are regressive; that is, low-income customers disproportionally purchase the near- or past-date foods. Except for infant formula, federal law requires no food dating, though that varies by state. If a date is used, the calendar date must give the month, day, and year, as well as "use before" or "best by." "Sell by" dates are for the grocery stores, which tell the employees how long to display the product. The "use by" and "best by" dates are to show quality, not safety. While it is well documented that the misinterpretation of food labels leads to millions of pounds of waste each year, consumers continue to interpret the date, regardless of whether it is "best by" or "use by," as the date by which the food should be thrown in the garbage (Leib and Gunders 2013; Gunders 2012). The Food Safety and Inspection Service of the USDA suggests the length of time and at what temperature the items should remain "good" past their respective expiration dates. The laws

that state what foods can remain on the grocery store shelves or are required to be removed past its stamped date vary widely by state, and many states have no additional food dating regulations beyond federal. Similarly, emergency food providers are typically seeking any and all available foods. The use of past-date foods is increasingly common; food banks and pantries often receive foods after a grocery store has pulled product from the shelves, usually at or near its package date. Frequently, regulations are in place to protect the market, rather than the public, and the cost of compliance varies based on the size of firm (Antle 1996, 2000).

Food Waste

Secondary to the issue of hunger is that of food waste – the pantries are able to intercept goods (both perishable and nonperishable) that might have otherwise been wasted, in the same vein as salvage groceries but with a social welfare mandate. Those goods are used to assist a hungry population and, given the rising interest in food waste, even more food is expected to be recovered in the future, some of which will be redistributed. Like in the traditional food system, the variety of goods available to the recipients is much broader than before, especially as more emergency food is cooked at home. Private standards from grocery stores, for example, can reduce costs and risks in the supply chains, but the supply chain does not always conclude at the grocery store – it continues to individual homes, restaurants, catering companies, churches, and a multitude of other places before donation. Many food pantries also accept fresh fruits and vegetables, which present numerous opportunities for microbial contamination from farm to processor to consumer. Each farmer and grower has his or her own methods for keeping food safe from farm-to-fork, some of which are superior to others.

Given their perishability, fruits and vegetables are wasted at the highest percentage overall but, given their high nutritional value over the regularly donated nonperishables, they are rising in interest at the food pantries and banks. It is possible that food waste will be reduced when consumers better understand when food is actually

“bad” and buy “imperfect” fruits and vegetables, though emergency food already consists of unsaleable produce and past- or near-date dairy products. “Food loss at the retail and consumer levels in the United States includes 14.8 billion pounds of fruit and 23.4 billion pounds of vegetables, valued at \$15.1 billion and \$27.7 billion, respectively, in 2008 retail market prices” (Buzby et al. 2011, p. 492). Those numbers are likely overestimated due to the share of food that is donated or sold at deep discounts rather than truly wasted. While food retail business managers want to reduce food waste and loss, the goal of the corporation is profit.

Corporate Social Responsibility

Corporate social responsibility plays a curious role in the distribution of emergency food, as many grocery stores receive tax credits and good social will by donating their near-date and slightly damaged items to food banks and food pantries. In most instances, the food pantries that are permitted to receive food from the large grocery chains must be part of the Feeding America network. Grocery firms determined, likely via cost-benefit analysis, how to reduce financial loss of the unsaleables, as “the social responsibility of business is to increase its profits” (Friedman 1970). Yet, the donated items are a direct result of grocery management’s notion that the items are good enough for those without means but are unacceptable for store shelves. Research has shown that an ideal level of CSR exists for each firm, based on characteristics like size, research and development, and even consumer income, among other variables (McWilliams and Siegel 2000, 2001). The authors assume that the purpose of CSR is to maximize profit but also that it is a form of investment.

In the case of emergency food, the profit motive exceeds its ethical and philanthropic components. For some major chains, the donation of near-date food comes as result of the corporation’s attempt to “address a growing need.” Yet, the program is described as a way to “limit the amount of food that might otherwise have to be thrown away, reducing food waste, and saving money on waste disposal” (Delhaize Group 2012, p. 84).

The key part of this description is financial, as the food does not have to be (and is not) thrown away. Even with the Good Samaritan Act, one can understand the level of detail needed for farmers and grocery stores to donate mass quantities of foods. Accordingly, one of the ethical components of CSR is to recognize and respect new ethical and moral norms, as well as prevent norms from being compromised in order to achieve corporate goals. This seminal entry continues to describe ethical responsibilities as the obligation to do what is “right, just, and fair” (Carroll 1991).

But what is “right, just, and fair” is variable. If the donated foods are “good enough” or “safe enough” to feed to one group of people, then they should be good enough for all groups. More importantly, if the policies are designed to prevent waste, then the grocery stores would be more prudent in their purchasing – but that could mean less profit, an output also determined by Aupperle et al. (1985). However, an analysis of supply chain CSR activities shows reduced transaction costs and risk but also increased profit (Cruz 2009). Recognizing that the food industry’s corporate social responsibility strategies lengthen the supply chain, health and safety are key dimensions in the food supply chain framework (Maloni and Brown 2006). The authors’ detail on this dimension include terrorist threats, traceability, labeling, and healthy lifestyles, and conclude the section by addressing the role food companies play in combatting hunger. Finally, as they suggest future research into the food industry and an examination of practicing established standards, public concern regarding supply chain CSR deficiencies are included, though emergency food is absent. No matter the reasons, grocery stores are key components in shifting America’s fight against hunger and food insecurity.

Food pantries across the country colossally depend on those philanthropic endeavors from grocery stores to farms to individuals, though not all food that is “recovered” and distributed to the emergency food system is necessarily saved from the dumpster. Given the lack of regulation and formal recommendations to the food pantries, personal beliefs regarding food safety prevail at the pantry level. Overwhelmingly, the major foodborne pathogens (*E. coli* O157:H7,

Salmonella, *Campylobacter*, *Listeria monocytogenes*) are attributed to fresh foods, from pork, beef, and chicken to sprouts, fruits, and seeded vegetables to dairy products. As food banks and food pantries seek to increase the amount of fresh foods (i.e., perishable items) that they distribute, understanding how to keep them safe becomes increasingly important. At the least, and perhaps most importantly, guidelines that articulate how to be compliant with the Good Samaritan Act and prevent contamination should be available, rather than the current reliance on reactionary efforts in the event of a foodborne illness outbreak. Similarly, a shift in food safety culture is likely more challenging in institutions that are older, making such information increasingly critical (even if not regulated by law).

Policy Concerns

There remains a tradeoff between concerns (and policies) regarding food safety, food security, and nutrition, given the prospective increased risk of foodborne illness with those items. To that end, if increased regulations are found to be the best means to change behavior, their implementation could lead to the closure of food pantries due to cost or bureaucracy, increasing the number of hungry families and individuals. State and local health departments might be the best venue for encouraging or requiring formal procedures, though that shift could require legislative change.

While there are states (e.g., Iowa and Massachusetts) that require food pantry inspections and/or have more stringent rules regarding donation, their operating procedures and supply chains have not yet been analyzed. Those states would be an excellent place to begin to determine the effect of rules on food safety risk in the food pantries – as well as how they are implemented and enforced. If the rules and regulations are not enforced, they have little effect. The level at which regulations might make sense in any currently unregulated state or locality remains in question, as well as the capacity for lower levels of government to take on another institution to monitor. Regulations can be costly, to those who are targeted and those who must enforce them; in this case, it might be most

effective to operate under a pay-to-play scheme. For example, the food pantries that wanted to operate within the state would have to pay for an annual inspection by health inspectors, assuming an inspection is needed to execute and enforce the food safety guidelines.

Conclusion

Regardless of regulatory measures, the food pantry managers should take precaution in serving, storing, and distributing food, either using the new online food safety guidelines for food pantries, food handling information disseminated by the food bank or curriculum they might find elsewhere. Foodborne illness in the United States represents a burden of approximately \$36 billion per year, with a \$3,630 average cost burden per illness (Minor et al. 2014). These numbers could be reduced with knowledge and behavioral changes at multiple points in the food system, including the food pantry level. Conclusively, this newness of this field of research should not go unnoticed. Regardless of income level, consumers should have access to food that is safe, requiring all supply chain actors to do their respective parts. Unlike other food systems institutions, the food pantries are private (predominately faith-based) organizations that provide a public good; that designation does not mean they should be treated as outliers in terms of food safety and handling information.

Emergency food is a critical part of America's food system, though its safety goes largely unmonitored. The lack of regulation or federally established guidelines for protecting and distributing foods are especially troubling in the event of foodborne illness, as access and affordability of health care is limited for low-income individuals. While grocery stores establish corporate social responsibility policies, this entry explores whether they are motivated morally or ethically, or rather, the desire to increase profit.

Food Dumping

[Agricultural trade](#); [General Agreement on Tariffs and Trade](#); [World Trade Organization](#)

Introduction

The process of trade liberalization posed significant challenges to the countries undertaking it. Once tariffs were removed, the main risk was the eventual rise of cheap imports from other countries, especially in the food sector. Cheap agricultural imports could create an imbalance in domestic food production and affect food security if their cost was below the normal domestic price or below the cost of production: this phenomenon is what is commonly referred to as food dumping. However, when it comes to creating an official

definition, dumping becomes controversial, because of the disagreement about what is considered such, its effects and premises and its possible solutions.

Following the definition of food dumping in the context of trade liberalization, this entry will analyze in what ways is food dumping a problem and what are its causes, consequences, and solutions.

Trade Liberalization

Surprisingly, food has only very recently become part of the global trade liberalization process. In 1947, immediately after World War II, 23 countries signed the General Agreement on Tariffs and Trade (GATT), a landmark in the path toward free trade. This Agreement did not include agricultural commodities. A few decades later in 1994, the General Agreement on Tariffs and Trade enacted the Agreement on Agriculture, so bringing food into multilateral trade rules.

The Agreement on Agriculture (AoA) was the outcome of what was termed the “Uruguay Round” of the GATT, one of the most important trade negotiations. AoA’s aim was to substantially reduce tariffs and other barriers in order to promote global agricultural trade. Until then, average tariff levels tended to be considerably higher for agricultural goods than nonagricultural goods. The AoA, which is valid for every agricultural product, is based on three pillars, market access, domestic support, and export competition, and instituted three main changes in these areas:

- In order to increase market access for agricultural products, nontariff barriers hindering agricultural trade were reduced by 36% over 6 years and converted to tariffs to be more easily located and circumvented.
- Domestic support measures were reduced because they were the most distortive features of agricultural trade.
- To protect export competition, new export subsidies were prohibited and the existing ones significantly cut. They were considered highly distortive and uneven as they were not equally affordable for every country.

An important feature of the AoA is the special and differential treatment clause, which allows developing countries to make two-thirds of the nontariff barrier cuts over a longer period of time (10 years). Least-developed countries were fully exempted from reductions.

Dumping Definition

The definition of dumping is quite controversial: the World Trade Organization (WTO) explains that a product can be defined as dumped if it is “introduced into the commerce of another country at less than its normal value” (WTO n.d.). In such formulation, the WTO equally included the two outlines of dumping: price-based and cost-based. If the selling price of an exported product is lower than its price on the domestic market and/or in third-country market, price-based dumping is happening (WTO n.d.). Instead, dumping is defined cost-based when the selling price is lower than the production costs (WTO n.d.). Albeit both differing in theory and in practice, the two kinds of dumping are often considered one altogether in the literature.

Decades before the WTO became interested in the topic, the economist Jacob Viner wrote *Dumping: a problem in international trade* (1923), the first comprehensive treatise on dumping and a landmark for the following literature. According to Viner, dumping “commonly signifies selling at a lower price in one national market than in another.” According to him, the difference between import prices and costs of production was not always a clear indicator of dumping, as it is considered now.

Viner also cleared the confusion about dumping connotation: not only he distinguished dumping from price discrimination and price-cutting, but he classified it in three main categories:

- Sporadic, when it is unintentional or aimed at disposing occasional overproduction
- Short run/intermittent, when it lasts for months or years in order to develop a commercial relationship or counteract competition

- Long run/continuous, when it is aimed at maintaining full production or enlarging the industry’s potential

Viner theorizes that the first type is irrelevant in economic terms and the second one is potentially dangerous, while the third one is desirable. From consumers’ point of view, dumping is beneficial when long lasting since it ensures low prices; if intermittent, however, it can severely undermine the food security of populations affected. As far as producers are concerned, if the product is not manufactured in the country, dumping is advantageous, while, wherever there is competition, domestic production can be injured.

Two WTO agreements regulate dumping: the above-cited Anti-dumping Agreement and the Agreement on Subsidies and Countervailing Measures (Germanwatch 2004; WTO n.d.). The former regulates governments’ response to dumping by establishing a series of mandatory steps: governments should start an investigation to demonstrate the presence of dumping, calculate its extent (dumping margin), and prove it is causing “material injury” to domestic industries (WTO n.d.). Once each step is demonstrated, anti-dumping duties can be imposed on the exporting countries by the recipient. During both the Tokyo Round (1973–1978) and the Uruguay Round, clear procedural rules for conducting dumping investigations were established, providing the correct method to determine dumping and injury margins.

The Agreement on Subsidies and Countervailing Measures aims to calibrate the use of subsidies and regulate the counteractions against their negative impacts.

In What Ways Is Dumping a Problem in Agricultural Trade?

Albeit few authors do not recognize dumping as a problem, considering liberalization and perfect competition intrinsically positive for international trade, the problematization of food dumping is threefold.

Antidumping (AD) Laws and Measures Are More Problematic than Dumping Itself

Several authors blame antidumping laws of being protectionist and anti-competitive, drawing from the assumption that protectionism in international trade is counterproductive (Niels 2000). AD measures are often used as a means of retaliation between countries, not to counteract real unfairness in trade. Therefore AD is often unjust against foreign exporters while turns a blind eye toward the poor competitiveness of domestic producers affected by dumping (Niels 2000; Aggarwal 2004). Moreover, AD investigations themselves are biased toward domestic plaintiffs because dumping margins can be easily inflated and authorities often use the “best information available” (p. 480), usually provided by domestic producers (Niels 2000).

Niels and ten Kate (2006) were the first ones to analyze which countries enacted AD laws more often. Even though the literature is mainly focused on developed countries, AD-user countries changed over the years involving developing countries more: for them AD can be, in some cases, a means of retaliation against both developed countries and developing countries, perceived as more direct competitors. Moreover, Niels and ten Kate (2006) claim that the outcomes of AD investigations are influenced by politics: the larger the industry complaining, the higher the possibility of finding dumping evidence for the investigators.

Zanardi (2006) follows on the analysis about the geographic distribution of the phenomenon: in 1904, Canada was the first country to adopt AD laws, but almost a century later, in 2003, 98 countries in the world have enacted measures against dumping. The fact that both developing and developed countries are present in this group shows that the narrative of victims and oppressors is not applicable. Moreover, developing countries used AD mainly as a form of retaliation against developed countries (73% of cases between 1981 and 1987 and only 33% between 1995 and 2001) before using them against developing countries and countries in transition (35% and 32%, respectively, between 1995 and 2001) (Zanardi 2006).

Liberalization as the Problematic Context Where Dumping Grows

Liberalization is placed in the context of globalization, a process aimed, among other things, at solving imbalances in production and consumption. Such a process was not entirely successful, since it presents several side effects, one of which is food dumping.

This section will point out how food dumping is problematized in the context of liberalization: the underlying assumption is that if liberalization is found to be a problem, so is dumping.

As the Food and Agriculture Organization (FAO) (2003) points out, liberalization in the food sector is more likely to hinder developing countries than developed ones, since the former are bigger importers of agricultural products, from which they are often highly dependent. Moreover, it is not supported by clear evidence that liberalization helps poor countries in eliminating subsidies and tariffs hurting them. Moreover, FAO states that AoA objectives of increasing agricultural trade, reaching price stability, and helping developing countries have not become true; in particular, developing countries may have suffered even more due to the increased competition. Broadly speaking, most of WTO agreements are blamed of being uneven toward developing countries as they fail to acknowledge the different economic and cultural weight of the primary sector in developing and developed countries. Consequently, they fail to address food security risks and to be tailored according to developing countries' requirements.

WTO's work on free trade has also been criticized for unevenly increasing the volume of global trade. The benefits of WTO membership come from liberalization: only in reaching a high level of liberalization will it be possible to gain advantages in terms of trade flow. However, developing countries had exemptions (special and differential treatment) in this field which allowed them to keep more barriers to trade than developed countries. On one hand, this was beneficial since abruptly removing tariffs would have been detrimental, but on the other hand, it did not allow them to fully experience the advantages of a complete liberalization.

Different Weight of Political and Legal Power of Each Country in the International Arena

Food dumping is counteracted by imposing countervailing measures on the country that dumps, but small countries often do not have the political power to do so (Murphy et al. 2005). Imposing tariffs on a product coming from a big and politically powerful country can be quite risky for a small country with limited influence in the international arena which depends on a single country for food imports (Murphy et al. 2005). Therefore, it must be made easier and less risky for those countries to challenge dumping, but WTO might not be the right body to address this issue because of its own internal power imbalance, which favors bigger countries with higher financial contributions. Other boards, such as the United Nations Committee on Trade and Development, may be more suitable for the job.

Since political power is strongly connected with the legal power of a country, Bolton (2011) supports the need of a fair legal empowerment of governments in order to ensure an effective counteraction of dumping. He defines legal capacity as the availability of “institutional, financial, and human resources” (p. 79) to engage in a court case, and he proposes the adoption of the “heightened scrutiny” (p. 66) method to reduce legal capacity’s importance in pursuing dumping investigations.

Dumping’s Reported Causes and Consequences

The causes of dumping, which may change for different foods and are influenced by different countries’ specific socioeconomic conditions, are the following.

Subsidies

The strongest denouncers of agricultural subsidies as food dumping’s main cause are non-governmental organizations (NGOs). According to Oxfam (2005), subsidies are responsible for encouraging oversupply of agricultural products which results in distorted international trade and depressed prices. When artificially competitive farm goods are dumped in developing countries,

they undermine the livelihoods and the food security of small-scale farmers, who earn less because of unfair competition. Uneven competition also hinders developing countries when they export since they lose market share for not being able to compete with the prices of dumped goods.

Conversely, FAO (2003) on one hand claims it is not legitimate to state that subsidies are hurting the poor, while, on the other hand, it admits subsidies’ inefficiency is true and acknowledges a causal link between subsidies and dumping. Moreover, it is not supported by evidence that liberalization effectively helps poor countries by eliminating subsidies that hurt them (FAO 2003).

However, while subsidies are surely responsible for dumping if they are essential for production, such as in the case of cotton and sugar, this cannot be generalized to every produce (Wise 2004).

Lower Production Prices

The naturally lower food production costs in different countries are identified as another cause of dumping. As an example, shrimp production in India is easily cheaper than in the USA because of higher raw material availability and cheaper labor. For the same reasons, the US rice industry has lower costs of production than the Mexican one.

In this case, the problematization of dumping is almost absent, since the cause is identified with a completely justified difference in the economics of food production.

Market Failure and Market Concentration

“In the case of U.S. agriculture, market failures cause dumping” (IATP 2004), and in turn market failure is originated by oligopoly of few companies in the food sector, which eliminates competition and leads to overproduction and low prices.

Murphy et al. (2005) echo this theory claiming that subsidies are responsible for price-depressing oversupply but they are only a symptom of a much deeper market failure.

Market concentration is listed among the causes by Rosset (2006) as well, who blames not only subsidies but also the elimination of supply management and price support policies in the USA and the EU. In particular, he stresses the point that

although several authors helped to create the confusion about subsidies and dumping, “blaming subsidies for low commodity prices is actually to reverse cause and effect” (Rosset 2006, p. 43).

The Consequences

Since the presence of injuries to domestic production must be recognized in order to start antidumping procedures, if dumping is happening, it is consequently acknowledged that domestic production is damaged. Injuries to domestic production are hence one of the consequences of dumping, as well as serious threats to food security.

While these consequences are recognized, the literature is divided over dumping's impacts in the short or long run. As mentioned above, Viner (1923) acknowledged the dangers of dumping when short-lasting, while it praised its advantages in the long run. Niels (2000) and Ritchie et al. (2000) highlight that dumping can increase the importing country's welfare because of the availability of cheap goods in the short term. However, they admit that in the long run “the domestic food productivity growth is more effective in stabilising developing country food security in the regular course of economic development, than the reliance on inexpensive food imports” (Ritchie et al. 2000).

Conversely, other authors and NGOs claim that dumping has disastrous consequences both in the long and in the short term, as it undermines domestic industry and food security of the importing country.

Germanwatch (2004) blames dumping of threatening the human right to food since it can stop at any moment, leaving consumers highly food insecure.

Moreover, dumping undercuts small farmers' revenues and can force them out of production, especially those in the Global South (Murphy et al. 2005).

How to Counteract Dumping

Food dumping's solutions are threefold: some authors advocate for a reform of AD measures, and others claim the urgency of a reform of subsidies, while others argue that a broader reform is needed.

AD Measures Reform

The primary rationale behind the execution of AD law is more political than economic and “external pressures such as import penetration and balance of payment deficits also exert a considerable influence on the use of AD” (Aggarwal 2004, p. 1053) in developing countries. International politics is involved too, since imports from less developed countries seem to be at disadvantage in the global trade for their lack of political power.

Subsidies Reform

A reform of agricultural support programs worldwide involving the end of export subsidies is called out loud by several authors, who advocate for the prohibition or limitation export subsidies and export restraints (Ritchie et al. 2000; Germanwatch 2004). According to Oxfam (2005), the EU should reduce its trade-distorting support by at least 70% to actually benefit developing countries' economies; on a global scale, the end of all protectionist measures of developed countries would strongly increase developing countries' net agricultural trade.

It is also claimed that since more transparency in subsidies is needed (Oxfam 2005), current and future subsidy reforms should assess their impacts on poverty reduction and food security in developing countries.

Broader Reform

1. Stop dumping and pay fair prices, by eliminating export subsidies or banning farm products below the cost of production, allowing all countries to protect themselves from dumping, and reintroducing minimum support prices for agricultural products (Rosset 2006). Eliminate economic distortions which make dumping possible, such as tariffs, subsidies, and monopoly power.
2. Regulate overproduction, since if you restore minimum price, the risk is that farmers will produce more to compensate (Rosset 2006). Because only big corporations are benefitting from dumping, a supply management strategy is needed to completely eradicate it, since the elimination of subsidies alone would not sufficiently increase prices paid to farmers (Murphy et al. 2005).
3. Make clear that subsidies are not the only cause and shift the attention to the real issue. Whether

its source is subsidies or oligopolies, dumping should be strongly counteracted with policy reforms aimed at reducing global commodity overproduction in key crops, a task which will require greater, not less, government intervention to reduce the structural tendencies toward overproduction and price depression. Finally, measures need to be taken at a global level to reduce the market power of transnational companies in the food sector (Wise 2004).

Conclusion

In conclusion, food dumping is debated because two phenomena fit into the definition, price-based and cost-based dumping, but they are consistently different processes regarding their causes, actors involved, and solutions.

Moreover, food dumping's social consequences are widely underestimated since it is not a problem in the global economy context but it only affects the trade of some agricultural commodities and the livelihoods of small-scale farmers in various circumstances. When addressed, it is often misunderstood as a purely economic matter preventing them to grasp the complexity of the issue. Without taking into account every implication of food dumping, an effective solution is not possible.

Food Ethics and Policies

Christian Coff¹ and Peter Kemp²

¹Centre for Ethics and Law, Copenhagen, Denmark

²Department of Education, University of Aarhus, Copenhagen, Denmark

Introduction

Food policy attracts considerable attention in public administration, among consumers, in the media, in food and agricultural research, and even in private organizations. In general, it is recognized that food production, food handling, and food consumption all have considerable impact on a number of issues such as health, economy, culture, and environmental sustainability. The recognition of the central role of food for society, the environment, and human beings has fostered multiple reflections on the role and extent of food policy. In this entry, focus is on:

- What is food policy?
- How is food policy interlinked with other policies?
- Which aims and ethical principles relate to food policy?

Policy and Principles

Considering the nature of food policy, it is reasonable to look into understandings of the last part of the concept, namely, *policy*. It is worthwhile to note that in English, unlike many other languages, a distinction is made between policy, politics, and polity. In short, polity refers to the political organization or form of a group. Politics refers to activities associated with governance of political questions. Politics as a decision-making process is concerned with the process of policy-making and therefore part of, for instance, power struggles about which policies to be conducted and implemented and of ethical and juridical evaluations of such processes.

When it comes to the concept of policy, most authors agree that the *raison d'être* of policies is to achieve certain desired outcomes. Policies state aims and goals to be pursued. As most organizations ranging from states to companies to civil society organizations have goals, they also have policies. Policies are hence applied from the macrolevel till the microlevel.

An example from food policy can illustrate this. A common desired outcome of food policy that can be found on all institutional levels from international organizations like the United Nations (UN), European Union (EU), and Codex Alimentarius (1979) to local levels like local can-
teens is that of food safety. The aims of food safety policies are manifold. Most evident is the aim to protect citizens' and consumers' health by avoiding diseases caused by food intake. This goal is also a part of UNs *Universal Declaration of Human Rights* (1948). Food safety is therefore linked to health, public health, and health policies. However, food safety is also important for consumers' trust in food and the food market and therefore interlinked with industrial and trade policies.

The example makes it clear that a desired outcome of a policy, in this case food safety, may serve different purposes. The case also underlines the interrelatedness of food policy with other policies. In the light of this, it can be debated if food safety should be seen as value in itself, as a value connected to other values, or simply as a tool to

reach certain outcomes and aims. The values behind food safety in this case stretch from economic considerations of the functioning of the market to the protection of individuals based on universal human rights which again are based on the ethical idea of the inherent dignity of all human beings.

The example suggests that policies and policy goals ultimately are based on values or principles even though they may not be expressed explicitly. In his famous definition of a political system, David Easton writes that “[A] political system can be designated as those interactions through which values are authoritatively allocated for a society” (Easton 1965, p. 21). Maurice Kogan (1975, p. 55) states that policies are the operational statements of values and statements of prescriptive intent. *Oxford Dictionary* describes policy as “a course or principle of action adopted or proposed by an organization or individual.” To summarize, it can be said that policies:

- State matters of principle (values, moral norms, ethical principles)
- Are prescriptive/guiding and focus on action
- Are authoritative statements

The last point refers to the fact that in order for a policy to be efficiently converted into action, it must be stated authoritatively. If a policy has no authority or is poorly legitimized, it cannot be expected to be implemented effectively. One way of legitimizing policies is to consider inclusive procedures during the process of policy-making (Röcklinsberg 2006), which belongs to the area of procedural ethics.

Development and Extent of Food Policy

With this understanding of the concept of policy, attention can be turned to *food policy*. Like any other policy, food policies state matters of principle and focus on prescription and action. This entry addresses the link between food policy and ethics and the question is therefore what are these matters of principle in food policy?

Food policy is not a recent term but a term with a history and therefore also a term with different meanings in different periods and different areas. Subscribing to a very broad understanding of the term policy, it can be assumed that most cultures in the history must have had some sort of food policy. Most societies, present or historical, do have principles about food and do take action to ensure that these principles are followed. Principles about food may, for instance, be based on religious, ethical, or economic principles.

In this sense, the idea of food policy has always been there even though it might not have been called food policy. However, both during World War I and World War II, the term food policy was much debated in public in the light of the restricted food supplies. Focus was on how to increase food supply. Food policy at that time was thus mainly an agricultural policy whose main principle was to ensure an efficient food supply to the population. Action was thus directed towards improving farming practices.

This understanding of food policy as an agricultural policy remains more or less unchallenged until the 1970s. The subsequent development of food policy has been subject to different interpretations. Maxwell and Slater (2003) goes as far as pointing to a shift of paradigmatic character in food policies, although this does not happen overnight but gradually over many years. They refer to an “old food policy” and the need for a “new food policy.” Whereas the old food policy focused on agriculture and rural areas, the new food policies place more emphasis on food consumption, health, and environmental issues. The shift in food policy is thus a focal switch from food supply to food demand (Maxwell and Slater 2003, pp. 532–534).

Their distinction between old and new food policies has been criticized by Lang et al. (2009, p. 8) for not doing justice to the extent of the policy challenge and thus being too simplistic. They argue for a more nuanced division of food policy into four periods starting from the 1950s that reflects how food policy is at first concerned with first food supply and what they call productionism; then, food policies focus on markets and third world development in the

1970s; from 1980 to 2000, environmental issues and food safety increasingly enter the food policy scene; and finally from 2000 and onwards, focus turns towards ecological public health. This development of food policies reflects different ethical concerns present in different periods. Today, it is fair to say that all concerns are present within food policy discussions.

Debate on food policy takes place in different arenas and focus varies accordingly. Compared to the historical outline above in a development and third world perspective, focus has been and still is mainly on food security and nutrition security. Food policy in the development context is marked by the founding in 1975 of the *International Food Policy Research Institute* (IFPRI) devoted to end hunger and malnutrition, and later, the Indian economist Amartya Sen (1981) gained international recognition for arguing for poor citizens' entitlement to food due to their vulnerable position in society. It is also in the early 1970s that food policy emerges as scientific field evident, for example, by the launching in 1975 of the academic journal *Food Policy*.

Thus, in the 1970s and 1980s, food security mainly became an issue discussed in relation to the third world, starvation, and poverty reduction (Timmer 2001). In the developed world as shown above, the shift in food policy is indeed a turnaway from food security and self-sufficiency that dominated the war periods and continued into the 1970s. Indeed, the issue of food security is taken for granted and considered as one of the successes of a market-oriented and (over)-efficient agricultural and food processing sector which has led to an overabundance of foodstuffs. This in turn results in new threats to health (like obesity and the associated diseases), and most recently also, the threats of food production and consumption to climate change are being recognized.

The shift in food policies is also mirrored in the renaming of ministries of agriculture to ministries of food and thereby underlining the move from the agricultural perspective to the consumer or demand perspective. Part of this change also reflects other social changes, for instance, there has been a massive migration from rural areas to

urban areas. On a more operational level, public food policies are in some countries mainly gathered in one governmental department (e.g., Germany and Denmark), whereas food policy relating to food safety and food production in, for example, the UK has been separated with reference to conflicting interests. Food policies are communicated by institutions in a number of ways like food policy documents, food regulations and laws, food certification schemes, advertisements, food procurements, etc.

In the light of the enormity and complexity of food policy, it can be debated if food policy should be divided into core areas that directly apply to food and those concerned with derivative or interrelated issues like health and environmental issues. Core areas that apply directly to food would typically be food production/supply or novel food. However, on closer inspection, the interrelatedness of these two issues with the demand side shows that, for instance, consumer health cannot be neglected in reflecting on how food supply and novel food should be developed and regulated.

It can likewise be debated whether food policy is to embrace other policy domains or if the other way around other policy domains should incorporate food issues into their policies. This may lead to controversies on the organizational structure and fights over policy domains in policy-making institutions.

Today, still broader and more integrative approaches to food policy are being proposed; an increasing number of areas are considered to be part of or incorporated into food policies. For the reasons outlined above, that food policy is an ambiguous concept. Recently, the education sector has been included in food policy, the aim being to promote basic food literacy and skills (see, for instance, *Public Health Association of Australia* [2009]) as part of a strategy to promote health. Also, climate changes have in recent years been introduced as a major element in food policy. Lang et al. (2009, p. 21) emphasize the embrative character of food policy, which makes it difficult to make a simple and concise definition of it. To simplify matters, at least 10 major traditional policy areas related to food policy can be identified:

- Research policy
- Agricultural policy
- Security policy
- Consumer policy
- Health policy
- Educational policy
- Environmental policy
- Trade and industrial policy
- Development and aid policy
- Transport policy

Efforts to Define Food Policy

The rapid changes in what is to be understood by the term food policy and the interrelatedness of the term have caused ambiguity as to the content and aim of food policy. Conceptual opacity is especially of concern for those involved in food policy-making. Clearly, one must know what food policy is about to make one. For this very practical reason, the challenge of defining food policy is most frequently undertaken by institutions involved in policy-making and less by researchers in academia. Chambolle (1988) refers to a *French Interministerial Group for Food Policy* set up in 1978 by which food policy was defined as the crossroads of problems linked with:

- Quantitative and qualitative adoption of agricultural production and food processes to meet the needs of well-balanced diets
- Food regulations intended to provide safe foods at value for money prices
- Distribution of food supplies, at both national and international levels
- Planning of research in agriculture and food processing, as well as in nutrition and food toxicology

This somewhat prescient understanding of food policy presents an embracive approach in which food policy includes agricultural research and production, food processing, healthy diet, food security, food safety, and affordability. Strictly speaking, in the sense that policy is used here, it is not a policy (principles and actions) but a list of areas that food policy applies

to. Chambolle (1988, p. 456) also refers to the definition by the *Organisation for Economic Co-operation and Development* (1981) who in their report *Food Policy* states that “the term food policy . . . regards the food economy, which takes account of the interrelationships within the food sector and between it and the rest of the national and international economy.” From these two efforts to define food policy, it can be concluded that very early on in the transition of food policy, there was an awareness that food policy touched upon numerous issues and was interrelated with other policy domains that contributed to the complexity of food policy.

Apart from the increasing awareness of the interrelatedness of food policy with other policies, some authors also point to societal changes as drivers in the shift in focus of food policies. Timmer (2001, p. 787) mentions three social changes with an influence on food policy:

1. Globalization and the associated commercialization. For instance, the upcoming of supermarkets and the changes it leads to on the food market.
2. Urbanization leads, for instance, to a more profound split between food production and consumption and increased food miles.
3. The technological development. New technologies like the biotechnologies pose new bio-ethical questions with importance for food policy.

However, some efforts to define food policy do not directly embrace the inclusive approach but point to a more narrow focus on food. Neil D. Hamilton (2002) describes food policy as “any decision made by a government institution which shapes the type of foods used or available – as well as their cost, or which influences the opportunities for farmers and employees, or effects the food choices available to consumers.” In the same line, the *State and Local Food Policy Project* (2005) suggests that food policy is “any decision made by a government agency, business, or organization which affects how food is produced, processed, distributed, purchased and protected.” In these two definitions of food policy,

emphasis is put on decisions by a government that exercises an influence on production, handling, and consumption of food whereas less importance is attached to the interrelatedness with other policy areas.

A final understanding of food policy to be mentioned here is that of Lang et al. (2009) which states that “we can define the study of food policy as of how policy-making shapes who eats what, when and how; and of whether people (and animals) eat and with what consequences.” They continue to describe the remit of food policy, which “ranges from how food is produced and grown, to how it is processed, distributed and consumed; from the structures that shape food supply, to those that determine health and environment; from the sciences and processes that unlock food’s potential, to the formal governance and lobbies that seek to control it; from the impact the food system’s dynamics have on society, to the way its demands are factored into policy-making itself.” In this understanding, emphasis is on the consequences of food policy for everyday life of food producers, handlers, and consumers as well as on the more systemic interrelatedness of food policy to other policy areas.

Major Matters of Principle in Food Policy

Given the long list of topics and goals that food policy embraces, it is not surprising that the list of ethical ideas and principles in food policy is quite extensive. It is not surprising that is not a common custom explicitly to supplement food policy goals with descriptions of basic ethical ideas and principles that these goals are based on. However, this is what this last part intends: to mention major ethical ideas and principles essential to food policy issues and goals.

Food security: The Universal Declaration of Human Rights states in article 25: “Everyone has the right to a standard of living adequate for the health and well-being of himself and of his family, including food” Food security concerns the demand side (consumers) and is based on vulnerability and integrity as the basic ethical principles. Rendtorff and Kemp (2000) argue that bioethics

and biolaw in a modern welfare state are based on four ethical principles that are linked to each other in a social framework of solidarity and responsibility. These four principles are the ideas of autonomy, dignity, integrity, and vulnerability. Within food security, the most important principles must be those of integrity and vulnerability. Concern about integrity is not only care for a person’s virtuous character but for the coherence of the life of that human being (Rendtorff and Kemp 2000, p. 39). Therefore, it includes both a psychological and a corporal dimension and the corporal dimension concerns “my own body.” This dimension is vulnerable: the human being is vulnerable in the sense that it can be hurt and submitted to risks that threats its integrity. Thus, the principle of vulnerability imposes an appeal for the protection of the human person’s integrity in a life span and a life space.

Therefore, the concepts of integrity and vulnerability are fundamental to legal systems protecting the rights of citizens. *Codex Alimentarius* (1979) states that “food purchases utilize a significant portion of the income of consumers, particularly low-income consumers, who often also represent the most vulnerable group and from whom the ensurance of safe, sound and wholesome food and protection from unfair trade practices is critical.”

Diet-related diseases: Food safety and nutritional behavior both focus on the risks of eating (see, for instance, Nestle [2002]). Food safety is based on the idea of the vulnerable consumer/citizen (Sen 1981). A more recent concept is that of nutrition security. Nutrition security exists when a person has a nutritionally adequate diet for an active and healthy life. The problem can be both lack of nutrients and access intake of nutrients. Also here, the principle of vulnerability is essential when protecting citizens and consumers from malnutrition. In the case of overnutrition like obesity, debates are among others on whether to blame the food industry or the individual. Proponents of the latter position argue with reference to the individual’s autonomy that the individual’s capacity for self-determination makes him- or herself responsible for the diet, whereas proponents of the first position argue that choice of diet is not an

autonomous act but it is coerced by, for instance, the food industry, supermarkets, culture, etc.

Also here, the idea of vulnerability invokes responsibility as a virtue and obligation. The EU food law (2002) places the primary responsibility for ensuring compliance with food law, and in particular the safety of the food, with the food business.

Food and consumer choice: The idea of a free market and more recently the notion political consumerism both point to the influence of consumers on the food market and food production practices. A central ethical principle at stake here is that of autonomy.

Individual autonomy is a complex concept that refers to the capacity to moral insight and to self-legislation. It also refers to decision-making without coercion as well as it invokes the idea of certain responsibilities. The right of consumers to make free choices is based on the ideas of autonomy and freedom (Coff 2006, p. 181; Mephram 1996), which calls for increased transparency and traceability in the food sector (Coff et al. 2008). Respect for autonomy is partly reflected in *Codex Alimentarius* (1979), which states that “no food should be in international trade which, is labelled, or presented in a manner that is false, misleading or is deceptive.” Respecting citizens and consumers autonomy in practice is dependent on the existence of a procedural ethics or discourse ethics that ensures citizens’ access to information and to participate at some level in policy-making.

Food research and production: Respect for living beings: Food and agricultural research must like all research comply with standard ethical research principles like informed consent (based on disclosure, understanding, voluntariness, competence, and consent), data protection, and nonmaleficence (avoiding causing harm).

Informed consent presupposes both cares for autonomy and integrity, and therefore, integrity is mentioned in the second medical Helsinki Declaration that claims that “integrity must always be respected.” Moreover, integrity is also a basic ethical principle in both food research and production as well as in the argument for the protection of animals and nature.

Food and environmental sustainability: Food policy has a strong link to environmental sustainability as food production is a heavy polluter and makes use of energy for production and transport (food miles). Beder (2006) presents the six major ethical principles within environmental protection that also apply to food policy: environmental sustainability, the polluter pays principle, the precautionary principle, the equity principle, the human rights principles, and the participation principle (procedural ethics).

Food and social justice: Codex alimentarius (1979) states that consumers should be protected from unfair trade practices. Fair trade is a concept that places social justice in a key position. Justice can be understood as a concept of moral rightness that focuses on fair distribution of benefits, risks, and costs without discrimination.

Summary

This entry gives an overview of food policy and major ethical principles that in the last decades have been proposed and advocated for in debates on food policy. Food policies touch upon a vast area of interrelated policies (like health, transport, environment, poverty, animal welfare, etc.) which makes of food policy a highly complex and diverse area. The entry opens with a description of the concept of policy and food policy and how it relates to ethical principles and values. The fourth section discusses some influential definitions of food policy. The final section contains a description of ethical principles and ideas of relevance to food policy.

Introduction

Ancient Indian natural philosophy of the Vedas offers a unique mythico-philosophical perspective on the role of food in nature, society, and the cosmos. In early Indian philosophies, food (anna) and breath (prana) are of a vital importance for the microcosmic (the body) as well as macrocosmic (nature and life cycle) “deities” or realities. In addition to their relevance for various disciplines of the body (e.g., yoga and vegetarianism), ancient Vedic teachings on food can also substantially inform contemporary environmental philosophy and ethics of hospitality.

Food in Ancient Indian Philosophy

For the Vedic philosophers, or the tradition of Vedism/Brahmanism, there existed five originary elements of the world: earth, water, fire, air, and ether (Aitareya Upanishad III). Given the natural relation between “food” (anna) and “eater” (attr), some Vedic philosophers included food among the originary elements and even attributed a primary role to it.

The Book XI of the Śatapatha Brahmana (Eggeling 1993) brings the legendary story of Bhrigu, the son and pupil of god Varuna. Being too proud and too confident, Bhrigu was sent to the jungle by his father. As Bhrigu looked to all four directions, he experienced horrible scenes of cannibalism, men dismembering men and eating their limbs. Upon his return to his father, Bhrigu receives Varuna's explanation: what he has seen were scenes from the yonder world, where men were representing angry souls of plants, trees, and animals, all of them seeking reward for being eaten and destroyed in their worldly lives. Bhrigu thus receives from Varuna a teaching about the interconnectedness of all of the living; he is instructed that the whole universe is nothing but the food. But at the same moment, the story of Bhrigu is also an early testimony for a deeper sacrificial awareness – not yet about vegetarianism, but about the elemental meaning of food and a lesson about the deeper meaning of food sacrifice (Ruben 1947). Later, this will lead to new ethical awareness, as exemplified in the teachings of Buddhism and Jainism and the traditions of vegetarianism in Hinduism.

In Taittiriya Upanishad III, there is another version of this legend. Bhrigu now learns the doctrine about Brahman and food. According to Varuna, Brahman is food, for it is from food that beings are born, on food they live, and to food they pass upon death. Given the Vedic meaning of Brahman as mysterious power of poetic formulation, or truth formulation (and later, in Vedanta, the absolute), and equating it with the food, Bhrigu is finally instructed by Varuna to practice austerities.

In the early Upanishads, food is recognized both as an originary material and as a spiritual substance: for TU II man is formed from the essence of food. Food is here listed among the other elements (space/ether, air, fire, water, earth) and worshiped as the highest of all, as Brahman itself. The poetic verse reads as follows: "From food, surely, are they born; all creatures that live on earth. On food alone, once born, they live; and into food in the end they pass. For food is the foremost of beings, so it's called 'all herbs.' All the food they'll secure for themselves, when they worship *brahman* as food" (Olivelle 1998).

The oldest among the Upanishads, the pre-Buddhist Brihadaranyaka Upanishad (BU) from the seventh to sixth centuries BCE lists seven kinds of food, being created by the father of the gods, Prajapati. Among the various foods given to the creatures, milk is of the foremost importance. Next, by following the Upanishadic teaching and by the means of the daily sacrifice, the sacrificer who knows this (in famous Upanishadic phrase, "ya evam veda") and follows this ancient teaching – i.e., the sacrificer which firmly establishes himself/herself in a Person/Creator – also knows the inexhaustible spiritual origin (food) of everything and thus receives the inexhaustible amount of (material) food. Here, it is clearly stated how the food serves as both a material and spiritual basis of all. Food and liturgical acts (rituals, including various daily practices) are thus interdependent and have ethical consequences.

Vedic god Prajapati used wisdom and "heat" (tapas, or "ascetic ardor") in his creative process. The same is expected from the humans when they imitate the creational and sacrificial acts of god(s). In the beginning of the BU, there is a story about two primeval deities: Death (Mrityu, m.) and Hunger (f.). From Death emitted water, then it solidified into earth, and from the heat (tapas), emitted in this process, fire was created. Air is also added to the elements. Mrityu began to eat everything he created, and thus, he becomes the eater of this world and the entire world is his food (Olivelle 1998).

Finally, there is another important correlation, namely, between food and breath (prana). In the BU V, both "Brahman is food" and "Brahman is life breath" are uttered by the Vedic philosopher. But food and breath (air) are closely interdependent. In a story about Pratriḍa and his father, Pratriḍa is instructed about reaching the preeminence as follows: all beings need food, and all beings likewise need (life) breath. This ancient Upanishadic teaching of the elements of food and air suggests that bodies subsist on a hidden cosmic or empirico-metaphysical *reserve* of food and cosmic wind, or breath. The ancient "wind-breath doctrine," as present in the early Upanishads, strongly attests for this phenomenon (Boland 1997). Finally, the whole universe is

nothing but the food. In his substance, man is now identical to the metaphysical food, or Brahman, the first and ultimate creator and consumer of everything (Geib 1976). As later exemplified in Maitrayani Upanishad VI (this Upanishadic text already refers to the teachings of Samkhya-Yoga), the whole universe is dualistically split between Purusha and Prakriti, as Eater and Food (Deussen 1938).

Another of the key early Upanishads, Chandogya Upanishad VI, reveals a cosmogonical story, closely related to food: in the beginning this world was one, without the second. In the process of becoming many, this primeval Being first emitted heat and then water (as a result of this cosmic perspiration), and finally, from the rain, it emitted food. Important teachings on the essence of food can be found also in Aitareya, Kaushitaki, and Mundaka Upanishads. Aitareya Upanishad I brings a cosmogonical story about hunger and thirst, which both affected the “deities” (i.e., various micro- and macrocosmic realities: human body and the cosmos). Immediately after they were created/emitted from the Self (atman), they fell into the cosmic Waters/Ocean. From these waters, food was created for them by this Self.

Food and Hospitality

Chandogya Upanishad (CU) VI (Ranade 1986) brings a teaching of Śvetaketu Aruneya, son of the famous Vedic sage Uddalaka Aruni. Part of this teaching is a philosophical discussion, or the Upanishadic doctrine on the beginning of the world and emitting of heat, water, and food from the primeval One, or Being. A reader of CU thus learns that everything in the world consists of heat (tejas), water (apas), and food (annam), i.e., three of the later five Upanishadic elements. These three elements now build, or enter, as it were, the human body: heat becomes speech, water becomes breath (prana), and food becomes the mind (manas). But then Śvetaketu is taught about the nature of food and the relevance of eating. Aruni instructs his son not to eat for 15 days. After fasting for 15 days, Śvetaketu returns to his father and he is further ordered to

recite the Vedas, but cannot fully remember them. The Upanishadic teaching thus shows how the human mind is essentially made up of food and how its cognition and memory are weakened without this vital element. But it is only later, namely, in the Taittiriya Upanishad and Kaushitaki Upanishad, that an ethical relevance of the doctrine of food can be observed for the first time.

As already shown, Taittiriya Upanishad (TU) brings a story about Bhrigu practicing austerities in order to learn about the Brahman. But in a contrast to his practices, Bhrigu is also instructed not to belittle food, not to reject food, and to prepare a lot of food – for everything in this world is based on food and man is firmly established only through food. This refers to cosmogonical contexts and thus to the cosmic or metaphysical level of thinking about the food. But TU III is also practical and concludes with a new ethics of food. According to this doctrine, no one should ever turn anyone away from one’s home without giving him the food. This is the Upanishadic vow of hospitality.

Kaushitaki Upanishad II brings a more explicit instruction on food and hospitality. A beggar, praying in a village, utters a vow: “I’ll never eat anything given from here” (Olivelle 1998). He then receives plentiful invitations (food) from the people. This teaching is a part of a teaching of the Upanishadic teachers Kaushitaki and Paingya; they both famously identified Brahman with breath. Now, in the Upanishadic teaching, giving alms is identified with giving offerings to breath. Namely, in Vedic thought, breath is the “best” among the five vital powers (hearing, sight, speech, thinking, breathing; in the Vedic Sanskrit, they are called “breaths” – after the first of them, breath). In CU VI, three main vital powers (thinking, breathing, and speech) arise from food. Both breath and food thus essentially and fundamentally refer to “life.” Four vital powers give offerings to breath, without being asked. This is now an act of primeval hospitality, as exemplified in this secret teaching (Upanishad). Nourishing vital (cosmic) breath, on a (micro)cosmic level, means being hospitable to the gift of life; giving food, or inviting the beggar to a house and

nourishing him or her, equally means to practice hospitality on a practical – i.e., ethical – level.

In the Book VIII of Śatapatha Brahmana, whatever evil there was, Prajapati had the power to drive it away by means of food, or sacrifice. The same was true for humans. Ultimately, all is food and eater in the circle of life – both in cosmico-sacrificial and in earthly practical domain, this precious gift of life is thus preserved with an act of a primeval hospitality. It is offered equally by gods and humans by ritualistic means and, ethically, by means of everyday rituals, such as various offerings (food, attention, later in Buddhism mindfulness) to beggars and strangers or all of them needing help and assistance.

Summary

In the ancient Indian philosophical traditions, we learn about the interconnectedness of everything. Food as an element has a deep philosophical as well as ethical relevance in the Vedic thought. It is both a material and spiritual substance of the world. Ancient Indian philosophy of the Upanishads closely relates food to breath. They both are of a vital importance for the life of a cosmos as well as of an individual. The Upanishadic teaching of the elements of food and breath suggests that “all this” (idam sarvam) subsists on a hidden metaphysical and empirical reserve of food in us. Food is the foremost of beings, as attested in verses from the TU II. Finally, food is also related to the emergence of hospitality in ourselves which, ritually and ethically, reveals as a vehicle of preserving life of the cosmos and life of all of the worldly creatures. It is in this hospitality that a sacrificial and sacred gift of peace can be revealed.

Introduction

Food justice is the idea commonly associated with the ethical framework under which access, distribution, and participation on issues regarding food are discussed. However, to provide a single and clear definition of food justice would be as difficult and as challenging as any other ethical endeavor that deals with the concept of justice. This entry focuses on providing the different angles under which food justice can be understood or defined and the possible challenges that such attempts could face. The issue of food justice opens the door to a series of questions that will inform any kind of definition that the reader may have. Do we have a right to food? If we do, who is responsible to satisfy that right? Should the actors involved in food issues be regarded as subjects of charity? Is food a domestic issue or an issue that concerns the international community? What obligations come with the right to access food? How should food be redistributed? Who should oversee such redistribution? Is food justice an issue of outcomes or of intentions? This and other similar questions are explored in this entry. To address the issues under consideration, this entry will present the different formulations of the idea of food

justice under the light of four of the major ethical theories, while the final section will focus on the dichotomy between domestic and international spheres in issues of food justice and how issues relating practical circumstances could put pressure on the notion of intervention.

Food Justice for Utilitarians

In ethical theory, one of the most recurrent debates happens between deontological and consequentialist theories. Utilitarianism is one of the leading representatives of the latter and throughout its existence has had different formulations; however, some of the main characteristics of the theory can be presented based on the works of two of its most classic proponents, Jeremy Bentham and John Stuart Mill. For Bentham, humanity was subordinated to the will of two masters pain and pleasure (1780). According to his analysis, we always act under the premise of rejecting the latter and pursuing the first. To achieve a life filled with pleasure, also known as a happy life, we must attribute utility or value to the consequences of our actions and try to foresee which actions will lead to the best possible consequences. In other words, which path of action will maximize happiness. Even though the search for happiness might sound like an individualistic endeavor, utilitarianism considers equality as a fundamental principle to follow before assessing any possible consequence of our actions. Because of that, any kind of analysis of the consequences of actions is not just about the maximization of the happiness of a single individual but about the maximization of the happiness of all the members of the society.

Extrapolating this formulation toward the field of food seems rather simple. Food justice in a utilitarian sense would be the provision of access, distribution, and participation on issues regarding food in such a way that the greatest level of happiness is achieved. This formulation seems to be quite straightforward and it would surely have some adepts. However, the problems of utilitarianism haunt any formulation of this kind. One of the main challenges a utilitarian might face would be the definition of happiness. Who defines what

happiness is? Is happiness the satisfaction of the minimum medical standards of nutrition? Or perhaps is about the participation in the process of decision of the distribution of food? How can we aim to achieve happiness at a planet level if we do not know what happiness is for everybody? Another challenge is the issue of the different perceptions of happiness for humans. What if one individual achieves a level of happiness of X by accumulating and consuming all the food in the planet while the rest of the members of the community only achieve a level of happiness of half X based on sharing the existing rations of food?

If one is to follow the logic of this formulation of utilitarianism, then one could end up with a position that defends the idea of accumulation of large amounts of food and other resources in the hands of 1% of the global population because that would amount to a higher overall level of happiness than another scenario where everybody on the planet would receive a small amount of the food provision in the planet. Another classical problem utilitarian ethical formulations might face is the capacity for foreseeing the consequences of every action we perform. We, as humans, are limited creatures, and the demand of perceiving all the possible consequences of our actions seems a rather demanding request from an ethical theory.

Food Justice for Deontologists

Unlike consequential theories, deontology claims that the morally correct path does not lie in making decisions under the premise that those decisions would create the best consequences in the future. An ethical theory developed by Immanuel Kant, it followed his understanding that by means of the powers of the mind, some of the most fundamental rules of the world could be found (Kant 1998). Notions such as time, causality, motion, etc. could be found by the use of reason. Truths on the domain of ethics were also available to humans by the use of reason. If reason alone can provide the moral answers one is looking for, a consequential analysis becomes unnecessary to

determine the right path of action. Kant's proposal focuses on providing a proper procedure for the determination of the moral thing to do. This procedure is known as the categorical imperative, and in one of its most widely accepted formulations, it consists of four steps that one must go through when confronted with a moral decision or consideration. The first step is to identify the act that we intend to perform and the reasons we have to perform it. The second one is to use the information provided in the first step and formulate a maxim or general rule of conduct out of it. The third step is to make that maxim go through a test of universalizability, which involves pondering whether it would make sense for everybody to follow such rule in a context where everybody would follow such maxim. Finally, if after the test the maxim still makes sense, then you have to evaluate if you can will yourself to act in that way in such a world. If the outcome of this analysis is positive, then your action is moral (2002, p. 37). Although complex and useful, the first formulation can and should be read in tandem with the second formulation to help us properly make ethical claims. The second formulation of the categorical imperative makes an important contribution to the procedure, by declaring that whatever action the individual is considering in performing, such individual must always act in such a way that humanity, the individual performing the action or any other rational being, is treated never simple as a means but always at the same time as ends on themselves (Groundwork, II.429). Even though more formulations of the categorical imperative could be introduced, for the sake of the analysis, this first two should suffice.

Food justice, in this ethical conception, would amount to something like the establishment of a set of universal regulations that have been found by means of following the procedure previously established under the premise that rational beings are to be treated not merely as means but always as ends. Examples of these rules would look like this: "Everybody ought to provide food for a person who is starving"; "Everybody ought, to tell the truth with regards to the amount of existing food in store at all times."

However, some problems may arise when making universal rules of this kind. With regard to the first rule, we can imagine a scenario where a mother is holding a piece of bread on one hand and her soon-to-be starving two young daughters on the other. In front of her, a starving elderly person that she has never seen is standing and demands the piece of bread following the rule stated before. Would it be possible to think that the mother has special obligations toward her daughter over a stranger? Would it be possible to think that when presented with the choice of saving an elderly person now or keeping the piece of bread for a few minutes to save her two daughters in the near future would still be a morally acceptable option? Following Kantian reasoning, her options are limited to just one, and that is to provide the piece of bread to the person starving in front of her regardless of any other consideration. This runs against many intuitions that people have regarding the duties we owe to our family members or even considerations toward the impact of the actions one person has over the future. Saving one elder person over two young ones may also sound counterintuitive to many people. Some recurrent criticisms toward Kantian theory focus on the disregard or lack of proper consideration to human notions such as sympathy or special considerations to the special bonds we share with family members, friends, partners, etc.

Food Justice for Virtue Ethicists

In the case of the previous theories, we are faced with possible definitions of food justice that amount to things that seem to miss the mark of many people's moral considerations. In the case of utilitarianism, the idea of achieving a higher level of overall happiness at the expense of most people seems to miss some of our ethical intuitions. In the same line, if one is to follow deontology and thus disregards the needs of your close ones in favor of the needs of a stranger, our moral intuitions do not seem to be properly tracked here either. Both previous theories can be accused of reducing human beings to mere decision-makers without understanding that many of our most recurrent

behaviors are a product of the repetition of certain actions. Virtue ethics is the theory inspired by the work of Aristotle and aims to provide humans with the proper tools to reach *eudaimonia* or roughly translated "happiness" (1956, p. 11). The term can be roughly translated as flourishing or well-being; and to achieve it, one must train oneself to be moral. The idea behind this theory is that finding the answer to a moral problem or dilemma is important, but our goal ought to be to improve ourselves not just our capacities to decide in a particular scenario. Virtue ethics aims to provide users with an account of what it means to become a just person, not just understanding how to do something just. In other words, virtue ethics aims to give us an understanding of how to develop a good character.

The way in which virtue ethics helps us understand how to train ourselves to be the best possible individual in different scenarios is first to identify three possibilities that are present when we act in the world. The first one is to act in an excessive way, the second one is to act in a deficient way, and the third one is to act in the most appropriate way all things considered. This third way is called the "mean," and to talk about ethics, in general, is to develop a good character, which in turn is developed by training ourselves to find the "mean" in the different scenarios that we might find. For virtue ethics, for example, if we were to face the issue of a mother having to choose who to give the last piece of bread, their two daughters or the starving stranger, the solution is not the salient aspect of the dilemma, rather, which action should one follow in order to improve their own character.

A noticeable problem in this account is that the focus is on the individual performing the action, not on the recipient of the action. The idea that whatever we do, we must do in order to improve ourselves seems to present problems as well. When dealing with issues of access, distribution, and participation on issues regarding food, we are necessarily talking about issues that demand interpersonal relations. All the individuals involved in issues regarding food ought to be regarded as relevant when making decisions that affect them. Our considerations about how to best distribute

food in the world or how to best identify the problems that our production systems face are not based only in a consideration of “what would make me a better person” but rather what is the best course of action for all the people involved or which action respects their dignity at the highest extent, issues that this ethical approach seems to not consider at length.

Food Justice for Value Pluralists

Another ethical theory that could provide insights when thinking about issues of food justice is value pluralism. The iconic author of this theory is W.D. Ross, and his goal was to overcome the problems that the Kantian and Utilitarian theories presented. For him, one of the main problems of the theories presented was that they did not consider how regular humans, not philosophers, deal with moral issues. For him some of the main problems that these theories presented were connected with the problem of monism. This problem amounts to the presumption that there is a “single, fundamental feature possessed of moral relevance” (Timmons 2002, p. 190). In the case of deontologists, autonomy seems to be this key feature, while for the defenders of utilitarianism, happiness would take its place. To be clear, Ross does not make a case to argue for the wrongness of those principles; rather his argument is that in different occasions different principles might be more adequate. In other words, for Ross it is necessary to avoid oversimplifications of what it means to deal with ethical issues in our everyday lives. Ethical problems arise precisely because simple answers are not always an option.

For Ross, the proper way to approach a moral dilemma is by means of considering and accepting the existence of six duties, some consequentialists and some deontological, that provide a closer account of our moral thinking. These duties are (1) duties that rely on my previous acts (fidelity and reparation), (2) duties based on the previous acts of other people (gratitude), (3) duties based on the fact or possibility of generating a fair distribution of goods (justice), (4) duties based on the

improvement of the conditions of other people (beneficence), (5) duties to improve myself (self-improvement), and (6) duties not to injure others (non-maleficence) (Ross 2002).

An account of food justice based on this framework would establish certain duties toward different humans on the basis of the list provided by Ross. Based on the first, one can establish the rule that we should always be honest toward the promises made in regard to the access, distribution, and participation on issues regarding food. Based on the fourth duty, one could formulate the rule that food should always be distributed fairly among different members of the society. While based on the sixth duty, the formulation of the rule would take the form of always providing access to food to humans in such a way that no harm is caused to others. The problems with this account of food justice would arise when considering all these duties at the same time; to exemplify this let us conduct a thought experiment. First, let us imagine that we have promised to provide X amount of food to countries A and B. The fulfillment of this duty would match with our duties of fidelity. Now, as the second part of this thought experiment, let us consider that in that very region, country B has suffered a devastating earthquake, and they are in need of immediate assistance. Based on the duty of justice, one would probably need to act in such a way that relief efforts are properly directed toward country B. But what if in order to prevent a massive famine in the devastated country B, one has to pull resources from the already promised resources to country A? Finally, what if by doing so, 10 people in country A would perish and 10,000 people in country A would be spared the same fate? Based on this account, in order to fulfill the third kind of duties, one would have to violate the fidelity and non-maleficence duties. Given that an ethical theory is expected to provide us with action-guiding principles, to guide us toward the violation of two principles to satisfy one would make for a controversial result. Another problem is the blind acceptance that Ross’ list of duties demands from us. If we are considering issues of food justice, why should non-maleficence be a fundamental duty while the duty to produce food is not? Ross is providing

a list of duties that not only are intuitively right to him but that seem limited when having to solve moral dilemmas among them. These issues put pressure on an account of food justice based on this ethical paradigm.

Food Justice for Right-Based Theorists

Another possible way to understand food justice is under the scope of rights. This kind of analysis was put forward by Wesley Newcomb Hohfeld (1920) in the early twentieth century and has since been reworked and fleshed out by thinkers such as Peter Jones (1994). Hohfeld provides an interesting and lengthy account of all the fundamental legal relations that inform our use of the term “right” showing a scheme of “opposites” and “correlatives” (1920, p. 36) where rights can be understood as claims, liberties, powers, and immunities. Following current trends in the field of ethics, this entry will focus on the first two to understand how these conceptions can relate to the notion of food justice. As Jones properly establishes, “to have a claim-right is to be owed a duty by another or other” (1994, p. 14). This means that a claim right implies the possibility of demanding the performance of certain actions from a duty bearer. Claim rights can be either positive or negative. The former means that an individual has the right to demand a certain action from a duty bearer, while the latter means that the individual has a right to not having another individual interfere in their lives. In the case of food justice, we can imagine a formulation of a positive claim right such that an individual or a group of individuals can claim to have a right to access food and the state or government is the entity against whose such claim will be presented, while a negative claim right would be closer to the right to not have the individual’s means of providing food, such as a farm, forcefully taken away. Liberty rights, on the other hand, are those rights that imply freedom from performing any duty due to the lack of a norm that binds the individual (Jones 1994, p. 17). Unlike claims rights, these rights are mostly of negative nature due to the lack of identification

of an individual or entity that ought to satisfy such rights in the first place. For example, an individual can have the right to grow any kind of crop that has not been banned in their country of residence and that the individual enjoys eating; let us think mangos. However, it is not clear that somebody ought to provide the seeds for mangos to satisfy the cravings or inclinations of the individual.

When considering issues of access, distribution, and participation on issues regarding food in the light of the rights theory, it would be helpful to consider some issues regarding the existence of rights. If one is to endorse this ethical position, identification of duty bearers becomes an important matter. For example, if one is to claim that people in the global south have the right to access food, and their governments cannot provide for that, would that make the rest of the world responsible for the satisfaction of such duties? If one is to follow that kind of reasoning, then an argument ought to be provided to justify the idea that other political agents, different from their respective governments, hold responsibilities in matters of food. What if we consider that the richest countries have a duty to provide food to countries in need, but doing so would generate problems to their own societies? What if their actions would not generate scarcity or problems to their own societies but rather prevent from further development? It is appealing to consider that the answer to situations like these would be to presuppose the existence of a global community where individuals and governments ought to share responsibilities for the actions and needs of others. However, this kind of scenario seems to appeal to an element of altruism that many times seems to be lacking at an international level.

Food Justice as a Domestic Issue or an International Issue?

Following from the last of the four accounts introduced in the present entry, the problem of the identification of the depositary of the obligations and

considerations to satisfy certain duties toward food justice is to be further considered. The classical reading of the concept of sovereignty is that of the ultimate authority (Britannica 2014) over a particular population within a particular territorial framework. This approach held itself through history, and even though controversy reigned about the exact meaning of the concept, it was widely held as a fact that states had the last word when it came to making decisions over its own population. After World War II, however, things changed. With the adoption of the UN Charter, respect for human rights became a principle as valuable and important as sovereignty (Popovski 2004). The tension between these two principles became more and more obvious as years passed by until the notion of sovereignty became something more. In 2001 the report of the International Commission on Intervention and State Sovereignty (ICSS) concluded that sovereignty did not mean just that states had the right to exercise authority over a particular population but that it also made states the first responsible agents in guaranteeing the protection of the human rights of the individuals under their authority. Thus, the expression “responsibility to protect” came into the public debate. Even more, the report proposed that if a state were to fail to protect the rights of the individuals under its authority, then it was the duty of the international community to intervene (2001).

In the light of issues of food justice, the question comes under a new light, and practical matters should become part of the analysis. If a country is facing certain constraints to provide for its own population, who exactly in the international community should act to solve those issues? If the answer is the United Nations, then we face certain difficulties. Political considerations also play a role in the United Nations, and the lack of funding is a constant shadow over the organization. If we were to think that the responsibility could shift toward the more opulent countries, what guarantees that the intervention of wealthy countries in countries where the state is unable to satisfy the rights derived of considerations of food justice of its own populations does not turn into an occupation? Is the international community a safe place to look for a different

depository of duties toward the satisfaction of our considerations of food justice? Issues like these permeate the entire discussion and are worth considering even after adopting any kind of ethical paradigm to consider food justice.

Conclusion

This entry shows that different accounts of food justice can be differently conceived under some of the predominant ethical theories in the field. To adopt one ethical paradigm implies to accept the challenges that have been raised for it. It is possible though, to accept that different areas of the idea of food justice, i.e. access, production, distribution, etc. could answer to different ethical paradigms independently. This, however, would require a great effort in balancing out the different possible contradictions that could appear in any given step. Finally, the identification of the agent responsible for the satisfaction of the duties of food justice is a problem in and of itself. To choose the domestic or the international level is to embrace a set of difficulties that need to be addressed. Sovereignty, colonialism, individual or collective moral responsibility, etc., are some of the issues that need to be answered when choosing one option over the other. Despite all that, given the social conditions of the world, it is fair to say that to engage in the debates on the ethical and political considerations and the proper meaning of food justice has become a moral responsibility to us all.

Introduction

The Roman town Pompeii was famous for its garum, a type of fish sauce. In one of the shops where it was sold, archaeologists have found a jar marked “kosher garum.” It must have contained garum prepared according to Jewish rules, excluding shellfish and other nonkosher ingredients (Berdowski 2006, p. 249). Obviously, it was labelled because it would otherwise have been difficult to distinguish from a nonkosher garum. In modern terms, being kosher was a *credence attribute* of the fish sauce. By this is meant that the customer herself could not determine whether the garum had the attribute or not; she would simply have to rely on the merchant.

Today, food labelling is much more common than in the Roman era. One reason for this may be that consumers are now more concerned with credence attributes of food. Another plausible reason is the increasing length of food distribution chains. Information easily gets lost somewhere on the road from the farm to the modern grocery store, and the modern urban consumer may not know much about how food is produced.

In addition to credence attributes, foodstuff has two other major types of attributes, namely, search attributes and experience attributes (Nelson 1970; Darby and Karni 1973). A *search attribute* is one that consumers can determine before buying. One can for instance find out the ripeness of fruit or the freshness of bread by squeezing them. An *experience attribute* is one that consumers can only determine after buying the product. A typical example is the taste of meat or fish. Credence attributes are those that the consumer cannot even determine after buying the product. One can divide credence attributes into two subcategories. A *detectable credence attribute* is one that can be detected for instance by chemical or bacteriological analysis although it cannot be detected by the ordinary consumer. Nutritional value and absence of pesticide residues are examples. An *indetectable credence attribute* is one that cannot even be detected through laboratory analysis. Country of origin, worker's health and safety in the production, animal welfare, and many

environmental aspects of the production belong to this category.

The need for labelling is greater for experience and in particular credence attributes than for search attributes. From an economic point of view, labelling can be justified as a means to reduce the information asymmetry between buyer and seller. From an ethical point of view, it can be based on the idea of the consumer's right to information.

Labelling can be either compulsory (legally required) or voluntary. Compulsory labelling is one of several methods in the arsenal available to regulators. Alternative methods include prohibition of products or production methods, liability legislation, and prohibition of certain messages on products such as false ascriptions of origin or unsubstantiated health claims. Voluntary labelling is primarily used as a means for companies to inform consumers of desirable product properties that are not subject to compulsory labelling. Voluntary labelling tends to have problems with its credibility. Certification schemes managed by credible, independent organizations have been used to solve the credibility problem of voluntary labelling.

Whereas mandatory food labelling has a strong focus on health-related issues, voluntary labelling schemes refer to much wider concerns. This should be no surprise, since food is much more than nourishment. Food choices are an integral part of many people's religious identity. They can also be expressions of cultural or family traditions. Increasingly, they are expressions of political standpoints in issues such as environmental policies, animal welfare, and workers' rights. Food has a role in expressing social and individual identities, and food labelling can help enable individuals to make the choices they want in these respects.

A distinction is commonly drawn between positive and negative labelling. Positive labelling reports the presence of an ingredient or an attribute ("enriched with vitamin C") whereas negative labelling reports its absence ("no added ascorbic acid"). The distinction between positive and negative labelling is fairly clear for specific ingredients, but less so for other attributes since

one and the same attribute may be described in either positive or negative terms. ("No imported ingredients." "All ingredients are from Swiss farms.")

Below, current labelling regulations will first be described, with an emphasis on international agreements. A brief section reports some results on the effects of labelling. This is followed by three sections discussing major ethical problems in food labelling, namely, arguments for and against labelling, the choice between mandatory and voluntary labelling, and finally the ethical choices of the food industry.

Current Food Labelling

Food labelling is decided in national (and European) legislation, but it is strongly influenced by an international framework that has been developed within the World Trade Organization (WTO) as part of its efforts to reduce nontariff barriers to trade. The WTO labelling rules are administered within two agreements, that on the Application of Sanitary and Phytosanitary Measures (SPS) and that on Technical Barriers to Trade (TBT). The SPS is devoted to risks to the health of humans and animals and the protection of plants against pests and diseases. The TBT deals with non-health issues such as fraud and misrepresentation.

The SPS provides minimal standards for health-protective labelling. Countries are allowed to adopt higher standards than those of the agreement, but only if these standards are based on scientific risk assessment and constructed to have as small impact on trade as possible. Decisions on what counts as science-based in this context are made by the Codex Alimentarius Commission that has been set up jointly by the Food and Agriculture Organization (FAO) and the World Health Organization (WHO).

The TBT agreement regulates labelling requirements on imports. It stipulates that such requirements "shall not be more trade-restrictive than necessary to fulfil a legitimate objective." The European Union has used this agreement to protest against the United States' mandatory

nutrition labelling, whereas the United States has used it against the European labelling requirements for genetically modified foodstuff.

Generally speaking, labelling requirements apply only to prepackaged food products, not to restaurant food. In what follows, some of the more common labelling requirements are summarized.

Ingredients: Major labelling systems such as those of the EU and the United States require that all ingredients be listed in decreasing order of weight. Certain allergenic food components have to be mentioned even at low doses, and even the risk of inadvertent contamination with an allergen due to the use of common processing equipment has to be stated.

Nutrition labelling is mandatory in most industrialized countries, with the exception of the European Union where it will only become obligatory in December 2016. Voluntary labelling of products that are healthy alternatives within their category (such as low fat sauce and high fiber bread) is promoted by several national European authorities.

Major legislations have a restrictive approach to *health claims* on food packages. Hence, the European legislation requires that health claims be based on reliable scientific evidence. Currently, this policy is put to test by the increased popularity of so-called functional foods that are marketed as health promoting (e.g., lowering total cholesterol or decreasing the risk of cancer) (Klompenhouwer and Van Den Belt 2003; Eden 2011).

Geographic origin labelling is usually not compulsory, but in the United States, country of origin labelling (COOL) is obligatory for fresh meat, fish and shellfish, fruits, vegetables, and nuts. This regulation was challenged by Canada, and in 2011, the WTO ruled in Canada's favor. The European Union has a system of protected geographic indications. Hence, cheese can only be named Gorgonzola if it was produced in a specific region in northern Italy, and Champagne has to be produced in the Champagne region in France (Cheftel 2005).

Irradiation is used to eliminate disease-causing organisms from certain foods. Labelling of irradiated food is mandatory both in the United

States and the European Union. Since the authorities consider irradiated food to be safe, such labelling has the sole purpose of furthering the consumers' free choice.

Labelling of food with *genetically modified components* is mandatory in the European Union, Australia, New Zealand, and Japan but voluntary in the United States and Canada.

Organically produced food, i.e., food produced according to certain rules excluding synthetic pesticides and chemical fertilizers, is subject to voluntary labelling schemes controlled by certification bodies. In addition, both the United States and the European Union have regulations stating which products can be marketed as organic.

Religious requirements on food production such as the Jewish Kashrut (kosher) and the Islamic Halal are in most countries subject only to voluntary labelling. (Israeli law prohibits the import of nonkosher food.)

Environmental effects of food production are subject to many voluntary labelling schemes, usually run by certifying agencies, many of which are connected with environmental NGOs. In most industrial countries, there are several competing such schemes, with various and not always transparent criteria.

Social responsibility in food production: The fair trade movement that formed in Europe in the 1960s imported food and other products from third world producers for sale in specialized shops. The purpose was to treat farmers and workers more fairly than what conventional companies do. Beginning in the 1980s, the main focus has shifted to labelling schemes that allow mainstream retailers to sell fair trade goods from third world producers. Voluntary labelling schemes promoting corporate social responsibility have had a central role in this development.

Animal welfare is subject to voluntary labelling in many countries, often as part of environmental or social responsibility labelling schemes.

Effects of Food Labelling

There is extensive evidence showing that nutrition labels make consumers choose more healthy food.

Unfortunately, it is not clear whether such effects are to some extent counteracted by compensatory consumption of other, less wholesome food. Do people add sugar or fat to increase the palatability of whole grain food? Or do they eat more of the (still rather unhealthy) reduced-salt snack than of a fully salted snack? The effects of nutrition labelling on total food intake are not known, and it is the total intake that matters.

Food labelling can also have effects on the behavior of producers. In the United States and Canada where labelling of genetically modified contents is voluntary, GM content is almost invariably unlabelled so that these products cannot be identified by consumers. In these countries the majority of items sold in grocery stores contain genetically modified ingredients. In Europe and Japan that have mandatory labelling schemes, food retailers have decided not to sell GM products and therefore such products are virtually nonexistent. Similarly, in several countries requirements to label trans fat contents have induced industry to reformulate their products so as to avoid labelling that may have negative effects on sales.

Arguments For and Against Food Labelling

The primary purpose of food labelling is to make the consumer more well informed. This can be justified with economic arguments, since markets function better if buyers and sellers have the same information. It can also be justified with ethical arguments such as arguments to the effect that the consumer has a right to the information needed to make well-informed choices according to her own criteria. Such a right to know would presumably not be restricted to health-related issues but could extend to other concerns such as animal welfare, environmental effects of food production, working conditions of farmworkers, etc. Consumers may very well end up making different choices based on a much wider array of considerations than those that food authorities pay attention to – and this rightly so since the authorities have a limited mandate.

Like all safety legislations, food regulation is subject to the potentially conflicting demands to protect the public and not to restrict their freedom of choice. Prohibitions or other measures against unhealthy foodstuffs are often accused of being paternalistic, i.e., reducing people's freedom for their own good. Contrary to some other regulatory measures against unhealthy food, mandatory labelling would seem to be immune against accusations of paternalism. Labelling does not restrict consumers' freedom of choice but instead provides them with information that they can use if they so wish when exercising that freedom of choice.

Some libertarians have claimed that mandatory labelling is an indefensible restriction of the producers' freedom of expression. However, although this argument has often been heard from tobacco companies, it has seldom been voiced in discussions of food labelling. Freedom of speech, as it is commonly conceived, does not exclude a duty to disclose information about the properties of a product to prospective buyers. In his *On Liberty* (1859, chapter 5), John Stuart Mill argued that mandatory labelling of drugs does not violate liberty: "Such a precaution, for example, as that of labelling the drug with some word expressive of its dangerous character, may be enforced without violation of liberty: the buyer cannot wish not to know that the thing he possesses has poisonous qualities." The same argument would seem to apply to food labelling.

Some types of labelling requirements have been criticized on the ground that consumers tend to misunderstand or misinterpret the information. This has particularly often been said about labels referring to irradiation or GM content. These are attributes that have caused much more worry among the general public than among experts on food safety and nutritional value.

There are two fundamentally different ways to see this from an ethical point of view. The consumers' right to know can be seen as valuable in itself, or it can be seen merely as a means to promote the right choices. According to the former viewpoint, mandatory food labelling can be defensible even if it makes consumers avoid healthy food that they wrongfully believe to be

unhealthy. According to the latter view, such labelling would be difficult to defend.

The use of labelling to solve problems in food production has also been criticized from a quite different perspective: labelling can be a way to shift responsibilities away from authorities and producers to consumers. If the aim is to avoid the cardiovascular diseases that trans fat gives rise to, why not just regulate fat composition in foodstuff instead of introducing labelling that shifts the responsibility to individual consumers? Since trans and non-trans fat taste the same, no plausible consumer interest in retaining the trans fat alternatives seems to be present (Resnik 2010). Similarly, if the aim is to avoid cruelty to animals, why then leave it to individual consumers to choose between foodstuff produced with and without such cruelty, instead of just outlawing the inhumane practices? If the aim is to reduce the negative environmental effects of farming, why not use more direct means than consumer choices of farm products? Labelling and consumer choice is only one of the strategies available to regulators, and in some cases, using this instead of other strategies has ethical implications that have not been sufficiently discussed.

Mandatory or Voluntary Labelling

One of the most contested issues in food labelling is the choice between mandatory and voluntary labelling. The critical issue is whether labelling should be mandatory for attributes that some but not all consumers wish to take into account in their food choices. In most countries the presence of allergenic components has to be labelled, and consumers can expect products without such labelling to be free of the common allergens. On the other hand, there is no requirement to reveal the use of synthetic pesticides. Consumers wishing to avoid pesticide-treated foodstuff have to look for food with (voluntary) labelling indicating that no pesticides have been used.

For discussing the choice between mandatory and voluntary labelling, it is useful to divide consumer concerns into three categories:

1. Consumer health-related concerns that are supported by medical science
2. Consumer health-related concerns that are not supported by medical science
3. Concerns other than consumer health

Concerns in the first category are usually supported by mandatory labelling, even if only a minority of the consumers are affected as in the example of food allergens. Concerns in the third category, such as animal welfare, environmental effects, the rights of farmers and farmworkers, kosher, Halal, etc., are seldom if ever supported by mandatory labelling. Some of these attributes, such as religious practices in food production, are usually considered not to be the government's business. Others, such as domestic animal welfare, concern issues where government has access to more direct means to impose its standards on food production.

Concerns in the second category are treated differently, sometimes inconsistently, by lawgivers. The United States is an interesting example of this. The country has mandatory labelling of irradiated food but not of food containing genetically modified organisms. In both cases there is popular concern about potential health effects, but these concerns are not supported by the mainstream science that the authorities rely on. It can be argued in favor of mandatory labelling in such cases that consumers who wish to avoid these products should have a right to do so. Mandatory labelling facilitates the exercise of such a right. (This argument need not extend to concerns in the third category. Concerns for one's own health may be particularly worthy of respect even if they are not based on science.) A major counterargument against labelling for concerns in the second category is that such labelling systems are costly. They largely deal with undetectable credence attributes, and therefore a system for tracking the origin of raw material throughout the production chain is needed. Arguably, the costs for this should be carried by the consumers who ask for the information. (This argument need not extend to the first category of concerns. Contrary to a wish to avoid irradiated food, being an allergic is not a personal choice and therefore more suitable for public economic support.)

The current European legislation that requires labelling of GM foodstuffs has been challenged on two fronts. On one side, there are promoters of a health-centered labelling scheme who claim that since there are no known risks with GM products, labelling will mislead consumers to believe that there are risks when there are in fact none. On the other side, some discussants maintain that since people may have reasons to avoid some but not all GM products, GM labelling should be more extensive and also specify the origin of the genes that have been transferred. An environmentalist may be against food produced from herbicide-tolerant plants with the help of herbicides. A vegan may refuse to eat vegetables that contain animal genes, a Muslim or a Jew food with porcine genes, a Hindu food with bovine genes, and Christian or secular Westerners food with canine genes. In order to make informed choices, they would all need to know more than just whether or not the foodstuff has been genetically modified (Siipi and Uusitalo 2008).

In the choice between mandatory and voluntary labelling, public expectations may have to be taken into account. In Israel and Saudi Arabia, it makes much more sense to conspicuously label pork than in countries where consumers wishing to avoid pork are used to reading through the fine-print contents list to make sure that no porcine ingredients are present.

Labelling Ethics from the Producers' Perspective

Both mandatory and voluntary labelling give rise to ethical issues for the producers and sellers of food. One of the most obvious ethical issues for food companies concerns the use of misleading or deliberately ambiguous information in labelling and – in particular – in off-label package texts and pictures. Some of the more prominent deceptive formulations are “evaporated cane juice” for “sugar” and “90% fat free” for “10% fat.” Pictures can be equally dishonest. Pictures of hens roaming free on a beautiful farmyard have been used on the package of products made from hens kept in battery cages. Pictures of cows in a Swiss landscape have been used to create the

wrongful impression that a cheese is of Alpine origin. Many countries have legislation intended to curb such practices, but even with such legislation, much is left to the producing companies' choice of an ethical standard.

The assessment of health claims in marketing is often ethically intricate. On one hand, untruthful or exaggerated health claims can seriously mislead consumers, and few health problems are solved by just choosing a single food product. On the other hand, nothing would seem to be gained by withholding information that can help consumers make more healthy choices. The strict restrictions against health claims in current legislations have been criticized for blocking information that could have contributed to saving lives (Adams 2010).

The “may contain” labelling of allergenic components poses an ethical dilemma for producers. Some producers provide such labelling to be on the safe side, even if the risk of allergen contents is slight (Mills et al. 2004). It would seem difficult to blame an individual producer for doing so. However, if all producers use this warning profusely, then it may become so common on foodstuffs that allergic consumers may end up neglecting it, thus putting themselves at larger risk.

Voluntary labelling gives rise to a market for labelling schemes. Corporations can choose among NGOs and certifiers who offer different labels at different costs and with different requirements for the label. At least one large corporation supported the formation of an NGO whose labelling requirements coincide with its own interests (Renard 2010). On the market for labelling schemes, consumers who buy the products are a third party with in practice very little information on the meaning of the different labels. The difference between labelling systems can be substantial. One ecolabelling organization allows its label to be used on all products with at least 25% ingredients that satisfy its certification criteria, whereas others have much higher requirements (Ballet and Carimentrand 2010). The lack of transparency in the market for ecolabels, fair trade labels, and other such certifications gives rise to legitimate worries whether some of these labels fully serve the ethical objectives to which they pay allegiance.

Summary

Food labelling aims at providing consumers with the information they need to make well-informed choices of food products. It is ethically highly contentious which characteristics of food should be subjected to mandatory, i.e., legally required labelling. Currently, mandatory labelling systems have a strong focus on health-related properties such as ingredients and nutritional value. In some countries, qualities such as GMO and irradiation have been included due to consumer demand of such information. Voluntary labelling schemes tend to focus on a wider range of qualities that may attract various segments of the population, such as environmentally friendly production, fair trade practices, or compliance with various religious requirements on food production.

Introduction

In general, food laws relate to a wide and multi-disciplinary range of issues including health and

safety, composition, science, labeling, and advertisement, but also abstract concepts such as culture and tradition come into play. In addition, food laws are no longer the exclusive domain of the government and public authorities, but also involve the influence of private actors that increasingly contribute and shape the development of food laws.

The purpose of this entry is to provide an overview regarding the different layers of food legislation in the EU. In order to provide a full picture of the legislative background, the development and evolution of food laws have to be considered. Also, the international dimension of food laws will be presented which in particular comprises international fora like the UN and the WTO. In the following, focus will be laid on the food laws of the EU by taking into account that the formation of EU food laws has been marked by different stages. The entry then refers to private food laws and standards emphasizing the integration of such standards with public law requirements. Finally, this entry will speak about the enforcement and controls of food laws.

Development and Aims of Food Laws

As indicated in a Codex Alimentarius Document (see FAO/WHO 2006), the emergence of rules concerning trade in foods dates back to ancient times. Early civilizations, such as the Egyptians, have rules in place determining the labeling applicable to certain foods. Also, the ancient Greeks and Romans have established food safety requirements. In antique Athens manufacturers followed certain standards when producing wine and beer. In Rome food has been controlled with the aim of consumer protection. Together with the development of separate countries in the Middle Ages, national legislation prescribing rules for the quality and safety of certain commodities started becoming more and more common. For instance, laws regulating beer purity were passed in Germany in 1516. In the nineteenth century, general food laws came into existence on the European continent. An example is provided by the Adulteration of Food and Drink Act 1860 adopted in

the UK prohibiting sales of knowingly adulterated food or food consisting of harmful ingredients (MacMaoláin 2007). Another example gives the Austro-Hungarian Empire with its *Codex Alimentarius Austriacus* developed between 1897 and 1911. The said document embodied standards and product descriptions for a broad range of foodstuffs which had been used as guidance for courts. This still existing (also known as Österreichisches Lebensmittelbuch – ÖLMB) system can be regarded as a predecessor of the Codex Alimentarius. Importantly, with the rise of science in the nineteenth century, the discipline of food chemistry was increasingly employed as an objective instrument for assessing food products' compliance with applicable rules (FAO/WHO 2006).

As indicated, the prime rationale for the establishment of law and rules for food is the protection of the consumer from unsafe, adulterated, and poor-quality products. The following section proves that these grounds serve still as the main objectives by current food laws and regulations. However – given the grown/growing globalized trade in food – focus is also laid nowadays on trade facilitation in the process of establishing food standards.

International Food Laws

United Nations (UN)

The International Covenant on Economic, Social and Cultural Rights (ICESCR) adopted by the General Assembly of the UN formulates economic, social, and cultural rights for the peoples. Notably, the multilateral treaty acknowledges the provision of food as a human right. In detail, Article 11 (1) of the ICESCR states that:

The States Parties to the present Covenant recognize the right of everyone to an adequate standard of living for himself and his family, including adequate food, clothing and housing, and to the continuous improvement of living conditions [...]

The UN Committee on Economic, Social and Cultural Rights has elaborated on the meaning of this recognized right to adequate food. In accordance with the General Comment 12 of the Committee in 1999, this right involves the availability

of a food in a quantity and quality sufficient to satisfy the dietary needs of individuals, free from adverse substances, and acceptable within a given culture.

Also, the UN Guidelines for consumer protection issued in 1985 and expanded in 1999 are of great importance as far as food safety is concerned. As it has been stated in Section 14 of the Guidelines, governments should intensify their efforts to encourage consumer organizations to monitor adverse practices, such as the adulteration of foods, false or misleading claims in marketing, and service frauds. Additionally pursuant to the Guidelines, consumer education and information programs should cover health, nutrition, prevention of foodborne diseases and food adulteration, and product hazards and product labeling. Finally governments have been called to give priority to areas of essential concern for the health of the consumer, such as food, water, and pharmaceuticals. Policies should be adopted or maintained for product quality control, adequate and secure distribution facilities, and standardized international labeling and information, as well as education and research programs in these areas.

FAO/WHO Codex Alimentarius

UN-specialized agencies such as the Food and Agriculture Organization (FAO) and the World Health Organization (WHO) have contributed to the development of international food law more specifically. This relates in particular to the creation of the FAO/WHO Codex Alimentarius, also referred to as the food code, in 1961. The conception of the code came partially in response to the increased need for harmonization of food standards in the view of differing domestic laws on foods acting as a barrier to trade. Consequently, Article 1 of the statutes of the Codex Alimentarius Commission enshrines the aim of protecting the health of consumers and ensuring fair practices in the food trade.

The Codex Alimentarius encompasses the formulation of international food standards, guidelines, and codes of practice that are achievable, taking into account the number and diversity of Codex members. In terms of content, standards developed under the Codex Alimentarius relate,

inter alia, to the areas of food composition, codes of hygiene and technological practice, evaluation and limitation of the use of pesticides, and evaluation of additives and veterinary drugs. Furthermore, the food code lays down an international numbering system of food additives.

The importance of the Codex Alimentarius at international level is reflected in UN Resolution 39/248 which provides that national governments should to the greatest extent possible adopt standards from the Codex Alimentarius or from other generally accepted international food standards when developing domestic food policies.

With reference to the individual instruments adopted under the Codex Alimentarius, "Codex Standards" may either refer to a specific foodstuff, as for instance the commodity standards on fruit juices or on milk and milk products, or may establish general standards as exemplified by the General Standard for the Labeling of Prepackaged Foods.

Codex codes of practice provide for production, processing, manufacturing, transport, and storage practices for individual foods or groups of foods. An essential code of practice developed by the Codex Alimentarius is the one on the General Principles of Food Hygiene which includes reference to the Hazard Analysis Critical Control Point system (HACCP) which constitutes the risk management method. Furthermore, the Codex Alimentarius has adopted the Code of Ethics for International Trade in Food establishing principles for the ethical conduct of international trade in food.

Other texts adopted by the Codex Alimentarius are Codex guidelines which can be distinguished into interpretative guidelines for the provisions of certain Codex standards and principles laid down for specific areas including risk analysis of foods derived from modern biotechnology or food import and export inspection and certification.

World Trade Organization (WTO)

International trading rules established by means of the various agreements under the World Trade Organization (WTO), namely, the General

Agreement on Tariffs and Trade (GATT), the Agreement on Trade Related Aspects of Intellectual Property Rights (TRIPs), the Agreement on Technical Barriers to Trade (TBT), the Agreement on the Application of Sanitary and Phytosanitary Measures (SPS), and the Agreement on Agriculture not only impact the global trading in food but also influence related legislation and regulations of WTO members.

Domestic laws regulating the labeling and packaging requirements of foods may obstruct international trade in foods. Equally, measures adopted by countries in relation to guarantee safe food may also ultimately constitute barriers to trade when put in an international context. Against this background, the SPS and TBT agreement were signed by WTO members to reduce the impact of above mentioned measures on international food trade.

Importantly, the SPS Agreement provides for the right of governments to adopt sanitary and phytosanitary measures which are necessary for the protection of human, animal or plant life, or health. However, the agreement requires that measures in relation to food safety as well as animal and plant health standards must meet a certain level of scientific justification due to their trade-restrictive and protectionist character. The agreement further promotes the adoption of SPS measures on the basis of international standards, guidelines, or recommendations. Accordingly, the SPS Agreement refers to Codex standards for food additives, methods of analysis and sampling, contaminants, and codes and guidelines on hygienic practice.

The TBT agreement grants governments the right to adopt technical regulations and standards such as testing and certification procedures or labeling requirements as long as they do not constitute unnecessary obstacles to trade, and the measures pursue legitimate objectives as listed in the agreement as, for example, the protection of human health or animal or plant life or health. Similar to the SPS Agreement, the provisions of the TBT agreement promote the harmonization of standards by demanding the use of international standards in the context of technical regulations.

European Union Food Law

The development of EU food law can be divided into several phases: the first phase is related to the adoption of legislation covering specific food products (vertical legislation). The second was characterized by the principle of mutual recognition and the third by the overhaul and modernization of EU food law reflected in the adoption of the General Food Law (van der Meulen and van der Velde 2008).

Early Food Legislation

In pursuance of the goal to establish a common market, the European Economic Community (EEC) that has become today the European Union relied extensively on the four freedoms: the free movement of labor, the free movement of services, the free movement of capital, and the free movement of goods. The evolution of food law in the EU especially before the 1990s was based on the concept of free movement of goods. On this basis, the European Court of Justice in 1979 established in *Cassis de Dijon* judgment the principle of mutual recognition of product standards with the effect that when a food is legally marketed in one Member State, it can be lawfully marketed in all other Member States.

The ruling laid down the foundations of a market-oriented approach based on the mutual recognition principle within the context of EU food law rendering detailed harmonization in terms of laws and regulations between Member States less necessary. Prior to the *Cassis de Dijon* case, the EU institutions adopted specific food-product standards as regards composition in order to harmonize the differing food laws of the Member States. Although a horizontal approach, i.e., legislation applicable to all food products, had then been preferred to the product-specific approach of harmonization, certain foodstuffs remain subject to such vertical EU legislation, e.g., fruit juices, chocolate, fruit jam, etc. (van der Meulen and van der Velde 2008).

General Food Law

The emergence of several food safety crises in the 1990s, especially in the form of bovine

spongiform encephalopathy (BSE) outbreaks, led to a fundamental change in EU food policy and legislation. The overhaul of EU food law was legally reflected in the adoption in 2002 of Regulation 178/2002, also known as the General Food Law (GFL).

The Regulation establishes general, overarching principles and requirements in relation to food law which are ultimately designed to protect human health and consumers' interests. Thereby, this EU food legislation shifts the focus from the harmonization of the common market to ensuring food safety. It incorporates a holistic approach termed "from farm to the fork" indicating that the principles outlined therein are applicable at all stages of food production and distribution. Against this background, Article 3 defines food law as:

the laws, regulations and administrative provisions governing food in general, and food safety in particular, whether at Community or national level; it covers any stage of production, processing and distribution of food, and also of feed produced for, or fed to, food-producing animals.

Given the establishment of a general framework of food, the Regulation's principles apply to food areas that were not subject to vertical legislation and only regulated through the mutual recognition principle.

As another novelty introduced by the GFL is the concept of risk analysis reflecting the acknowledgement by EU legislators that regulatory decisions in the area of food law should be underpinned by science. The risk analysis model is divided by the GFL into the components of risk assessment, risk management, and risk communication. The GFL also provided for the establishment of the European Food Safety Authority (EFSA), which represents the risk assessor, by providing scientific opinions and information to the risk managers. The European Commission and national authorities fulfill the role of risk managers predominantly. The process of risk management involves the weighing of policy alternatives by taking into account the results of risk assessment and other legitimate factors. Risk communication relates to the interactive exchange of information and opinions during the risk

analysis process and includes for instance the explanation of risk assessment results.

Following the adoption of the GFL in 2002, further legal instruments were included. The legislative texts take largely the form of regulations and therefore are directly applicable in EU Member States whereas previously EU food legislations were given through directives requiring implementation at national level. Regulations passed by the EU legislators to contribute further to the modernization of EU food laws included, inter alia, Regulation 1829/2003 on genetically modified food, Regulation 1935/2004 on food contact materials, Regulation 1924/2006 on nutrition and health claims or Regulation 1333/2008 on food additives, and Regulation 1169/2011 on food information to consumers.

EU Legislative Acts on Food Products

Besides the general framework laid out in Regulation 178/2002 and applicable to the whole food sector, the EU legislator addresses in other documents particular food products. Prime examples of such legislations are the EU framework Regulations on enzymes, food additives, and flavorings. In detail, the said framework Regulations provide for general rules on the conditions of use of these substances in food as well as marketing requirements including specific labeling standards.

Common to the structure of the framework Regulations is the establishment of positive lists that are incorporated in the so-called Union lists. The establishment of positive lists implies that specific food additives, flavoring substances, or enzymes can only be marketed provided they are included in the respective list. Otherwise, the products cannot be placed on the EU market. Being part of the Regulation, the positive lists can only be amended so as to include new food additives, for example, by following a legally defined authorization procedure set out in Regulation 1331/2008.

In general, positive lists constitute an important instrument in EU pre-market approval schemes that are found in legislative texts relating to other product categories. Accordingly, novel foods for instance regulated by Regulation

256/97 will first need to be scientifically evaluated by EFSA prior to their placing on the market.

The integration of pre-market approval schemes in EU food law entailing scientific evaluation reflects the strong scientific dimension of EU food legislation.

Private Food Laws

Scope

By contrast with requirements stipulated by legislative texts that may also be described as public law requirements and are binding on economic operators in the food sector, private food laws provide for rules that do not impose an obligation per se on operators. In other words, such private schemes constitute non-binding rules. However, these non-binding rules may nevertheless become binding by inclusion into a contract that binds the parties having concluded the contract (van der Meulen 2011). Due to the conclusion of the contract, obligations between parties come into existence with regard to the voluntary rules, and the parties are equipped with rights in case of non-compliance with the provisions of the contract, which then can also be invoked before courts.

Standards set by private entities concern food safety, food quality and production, or broader interests involving environmental aspects or corporate social responsibility. In particular, hygiene codes or codes of conduct serve as an illustration in this regard.

Also, often the term self-regulation is used for such kind of arrangements which has been, for example, defined by the EU in the interinstitutional agreement on better lawmaking as *the possibility for economic operators, the social partners, non-governmental organizations or associations to adopt amongst themselves and for themselves common guidelines at European level (particularly codes of practice or sectoral agreements)*.

The creation by businesses of own obligations in addition to legal requirements can have different motivations. Rationale behind private food schemes is to ensure food safety aspects and standards with the consequence of protecting liability

and product quality. By implication, this also helps to comply with legal requirements established by the public legislator. Private standards are also beneficial in terms of international cooperation by using private regulation in order to impose certain obligations on producers that work in countries with different legal requirements. Other aspects such as the promotion of general interests including corporate social responsibility can play a role when private standards are adopted by businesses (van der Meulen 2011).

Relation with Public Law

Mostly, private food laws relate to requirements that are found in legal instruments. In this way, private schemes interconnect with public law requirements. Conversely, legal instruments can refer to private standards. In particular, at EU level Regulation 882/2004 makes reference to standards developed by the European Committee for Standardization (CEN) in the context of methods of sampling and analysis. The CEN provides voluntary standards for industry and business. Another possibility found in public law vis-à-vis private standards is the requirement on affected parties to regulate for themselves. A prominent example in this relationship is EU Regulation 852/2004 that imposes the obligation to set up procedures based on HACCP principles (van der Meulen 2011).

Enforcement and Control

EU Food Law

The food scandals prior to the adoption of the GFL revealed that enforcement of food safety legislation was not functional and that the legislation on food controls requires improvement. Consequently, a legislative revision of enforcement and control procedures regarding EU food laws was also undertaken.

Article 17 (2) stipulates the principle that national authorities are responsible to enforce food law and monitor and verify that the applicable food law requirements are fulfilled by food operators at all stages of the food chain. Therefore, in the context of official controls, national

authorities are in charge of the inspection of premises run by food operators.

Despite this general obligation on part of the EU Member States, Regulation 882/2004 on official controls performed to ensure the verification of compliance with food law provides the Commission with supervision powers of national enforcement. Per the provisions of this Regulation, the Commission monitors the performance of national authorities with regard to enforcement.

Where the national authorities find non-compliance with relevant food law, Article 55 of Regulation 882/2004 provides the national authorities with several types of enforcement actions to remedy the situation. The imposition of sanitation procedures, restriction or prohibition of placing the noncompliant product on the market, monitoring and where necessary ordering the recall, and withdrawal and/or the destruction of the food are listed among the possible actions. One of the most stringent enforcement actions national authorities can apply is the suspension or withdrawal of the establishment's approval.

The Regulation further establishes that each Member State must lay down a system of sanctions for the infringement of food laws. These sanctions must be effective, proportionate, and dissuasive.

Private Food Law

As already implied in section “[Scope](#)” of this entry, noncompliance with private food standards can entail several consequences such as contractual fines as agreed in the contract between the parties.

To control the producer's compliance with the requirements set by a particular private standard, so-called certification schemes are applied. These certification schemes shall attest in principle that the “audited” producer complies with the given specifications of the standard. Normally, certification schemes are based on third-party control involving the provision of a certificate to the producer where compliance is proven (van der Meulen 2011). In contrast to certification systems, certain schemes exist on the basis of self-declaration (Commission Communication 2010).

Summary

This entry gave an overview of the major components forming food laws and regulations. In doing so, the entry distinguished in particular between international food laws, EU food laws, and private laws while taking into consideration the entanglement of the various spheres of food laws. The entry outlined first the development of food laws from a historical point of view. Then it presents the area of international food laws notably the UN contribution to the development of food laws, in particular through its agencies of FAO and WHO that launched the idea of an international food code, the Codex Alimentarius. As another actor at international level, the WTO affects international trade in food and the domestic laws of its members. This is in particular achieved through the SPS and TBT agreement. The following section dealt with EU food laws and its development in different stages. As explained, the adoption of the Regulation 178/2002 (GFL) led to a fundamental change in EU food legislation entailing significant legislative changes for the food sector in the EU Member States. Subsequently, this entry described the establishment of private food laws by business entities and their benefits. In the last section, the enforcement and control mechanisms to ensure compliance concerning food law requirements are shown in the context of EU food law and private food law. In detail, the enforcement and control apparatus under EU law is determined by Regulation 882/2004 whereas under private food laws certification schemes are of relevance.

In the future, food laws will have to continue evolving as quickly as possible to respond adequately to the upcoming scientific and technological developments in the food sector. These emerging technologies, such as nanotechnology enabling food industry to improve food products in terms of, e.g., taste or texture and thereby providing unprecedented opportunities to modify food products, entail fundamental changes in the food industry and hence potential risk for the consumers. Against this background, food regulators must be prepared to address these new challenges to food safety while not stifling innovation and research in the food sector.

lading archiving the contents of every inbound ship was an implicit reference to a point of origin and, therefore, a record of the distance food traveled. Not incidentally, in most cases, the further afield a particular good originated from the point of consumption, the more it was valued for its exotic qualities. Throughout most of human history, the market rewarded distance and novelty. The more miles traveled, the better.

By the late twentieth century, popular evaluations of food production had shifted into the new framework of global sustainability. An emerging emphasis on the environmental consequences of food production, initially inspired by Rachel Carson's *Silent Spring* (1962), fostered critical changes in how consumers evaluated responsibly produced food. Perhaps most notably, consumers now took an interest in reducing the distance food traveled between "farm and fork." "Buying local" and nurturing local "foodsheds" became progressive agricultural goals. As these trends coalesced, socially conscious consumers demanded to know more about the distance food traveled. They called this figure "food miles."

The name arrived alongside a virulent form of food politics. What was once an objective and morally neutral measurement between the points of production and consumption evolved into a value-laden proxy for eco-correct consumer behavior. Today, a debate with strong ideological overtones plays out – and in some cases rages – over the impact that food miles have on the overall environmental impact of food production. There is, for all the concept's popularity, currently no consensus on the extent to which food miles matter as a reliable gauge of sustainability.

The immediate history of food miles per se began with Dr. Tim Lang, former director of the Sustainable Agriculture and Food Alliance. Lang coined the term "food miles" in the early 1990s. The basic intention behind this idea was to develop an accessible gauge for how consumers might judge the carbon emissions released during in the production of a particular type of food product. Lang explained in 2005:

The idea behind food miles...was and remains simple. We wanted people to think about where their food came from, to reinject a cultural

Food Miles

James McWilliams

Department of History, Texas State University,
San Marcos, TX, USA

Introduction

The concept of food miles has been relevant for as long as humans have swapped food. Every bill of

dimension into arcane environmental debates about biodiversity in farms. . . . Food miles have rocketed in recent years. Between 1978 and 2002, the amount of food trucked by heavy goods vehicles (HGVs) increased by 23%. And the distance for each trip increased by over 50%. In 2002, food transport accounted for an estimated 30bn vehicle kilometres. (Barclay 2012, p. 2)

The upshot for the environmentally aware consumer, as Lang advised, was clear: “shop locally and buy local produce” (Lang 2005)

Lang’s emphasis on food miles as a measure of sustainable food production joined the quantitative efforts of Rich Pirog to pin down the precise extent to which food traveled in the global economy. Pirog, while working as the associate director of the Leopold Center for Sustainable Agriculture at Iowa State University, calculated in 2001 that the average distance that food travels between farm and table was about 1500 miles (Black 2008). Locally sourced food, by contrast, traveled a mere 44.6 miles. The difference in CO₂ output consumed by transportation between the conventional and local food systems was notable. Conventional food production turned out to use from 4 to 17 times more fuel than local food production in order to move goods from farm to table. The implication was, yet again, perfectly clear: buy food locally whenever possible (DeWeert 2009). Research by Pirog and Lang spawned a cottage industry of quantitative research aimed to map the miles traveled within regional and global food systems.

Mathematical computations on food miles, and the implications therein, soon translated into concrete consumer trends. High-profiled efforts to eat locally captured the popular imagination through glowing media reports. Before questions such as “what is local” or “do food miles even matter” were seriously examined, food activists joined bandwagons of advocates in pursuit of “the 50-mile” and “the 100-mile” diet fads, writing popular books, magazine articles, and blogs to chronicle their culinary adventures. Promoting the virtues of a diet that kept consumers tethered to local production while reducing reliance on fossil fuels, writers including Michael Pollan (in the *Omnivore’s Dilemma*) and Barbara Kingsolver (in *Animal, Vegetable, Miracle*) became the unofficial leaders of an unofficial food movement that sought not only to reduce food miles

but, building on that reduction, to reexamine the very basis of the entire post-World War II idea of food production. *Time Magazine* provided a capstone of sorts to this emerging movement with an article entitled, “Local-Food Movement: The Lure of the 100-Mile Diet” (Roosevelt 2006). In the forge of this critique, industrial food production – once the pride and joy of the United States – became enemy number one, at least for a small but vocal cohort of relatively privileged westerners willing to spend more to eat locally sourced food.

Several related developments emerged from this comparatively widespread quest for local food. The first was the addition of a single word that would jolt even more consumers to pay attention to food miles while anchoring the future of food reform. The word “locavore” entered the mainstream as the Oxford English Dictionary’s “word of the year” in 2007. The term was coined by the Berkeley, California, chef Jessica Prentice in 2005 as a way to describe, as Ben Zimmer, editor of the American dictionaries at Oxford University press, put it, “food-lovers [who] can enjoy what they eat while still appreciating the impact they have on the environment” (Safire 2008).

A second development to emerge from the food mile frenzy was a sudden spike in the popularity of farmers’ markets. According to the USDA, the number of active farmers’ markets in the United States rose from 2863 in 2000 to 7864 in 2012, an almost threefold increase. One study exploring why people chose farmers’ markets over conventional grocery stores found that 64% of the customers at farmers’ markets came to buy local produce (Wolf et al. 2005, p. 192). The website supporting Michele Obama’s “Let’s Move” initiative celebrated “access to fresh, locally grown foods” as the top reason for shopping at a farmers’ market. In many ways, farmers’ markets became the most visible evidence that the numerous goals promised by eating local were well within reach: eco-correctness, community cohesion, reduced food miles, and, of course, the hand of the farmer. Your farmer.

A third foundational change to emerge from the concerted effort to localize food production and consumption involves the cultural demonization of factory farming. The concentrated production of animal goods in industrial settings was

increasingly illuminated by locavores to be unsafe, unsanitary, inhumane, and devastating to the environment.

While effectively channeling the anger of conscientious consumers who were fed up with the industrial food system, the locavore movement – which was broadened and reimagined by food reformers into the Sustainable Food Movement – struggled to overcome its image of elitism. For a wide variety of reasons (including reduced scale), local food requires higher labor and production costs. Leaders of the Sustainable Food Movement generally confronted this economic reality with feet of clay and a tin ear. Many examples abound.

When Michael Pollan explained to the *Wall Street Journal* in 2010, at a time when the country was deep in a recession, that it made perfect sense to spend \$8 on a carton of locally sourced eggs, or when Alice Waters, executive chef and owner of Chez Panisse, chastised consumers for wanting “to buy Nikes, two pairs” rather than spend more on local food to “nourish themselves,” middle-class consumers came to feel that they were not so welcome under what Pollan called the movement’s “Big Umbrella.” Josh Viertel, former president of Slow Food USA, spoke highly of the need to be all-inclusive. He wrote, “Should we be a movement that meets the interests of those who are naturally drawn to us and who can afford to take part, or should we be a movement that meets the needs of those who are most dependent on our being successful – and who are most vulnerable if we fail?” Nobly, he declared his allegiance to the latter. Five months later, unable to blend the goals of slow food and high accessibility to it, he resigned amid considerable controversy.

Difficulties reaching a more socioeconomically inclusive audience did not prevent the Sustainable Food Movement from wielding the cause of local food as an ideological weapon in the war against globalization. In 2007, Vandana Shiva, an ardent Indian activist, wrote in *Manifestoes on the Future of Food and Seed* (2007) that “By eating local, we are taking power and profits away from global agribusiness, and strengthening our local food community.” Her outrage against the expanding global food chain, including its

dominance by multinational corporations such as Monsanto, was shared by Prince Charles who, in the same volume, touted local food production as a “significant challenge to the massed forces of globalization, the industrialization of agriculture, and the homogenization of food.” Once again, at the core of this critique was food miles.

As eating locally sourced food for environmental reasons became a well-established form of food activism, trenchant criticisms of food miles began to question to concept’s accuracy and viability. At the forefront of that criticism was a more comprehensive evaluation of the energy required to produce our food called a “life cycle assessment” (LCA). LCAs consider not just the distance food travels but, in so far as they can, other factors of production and consumption that are required to bring food from farm to table. Some of these factors include water usage, harvesting techniques, pesticide usage, fertilizer outlays, disposal and storage methods, packaging, crop drying techniques, and dozens of other inputs that consumers rarely think about when judging the eco-correctness of a food purchase. The reason why LCAs posed something of a challenge to the concept of food miles is that, when these other factors of production are taken into account, the distance food travels appears to play a relatively small role in the overall energy profile of food production.

Interestingly, one of the key figures to initiate the transition to LCAs as a better assessment of food’s “carbon footprint” was Rich Pirog, originator of the 1500-mile claim. Subsequent research he conducted found that, when it comes to food’s extensive supply chain, 45.6% of all fossil fuel used came from production and processing, 15.8% from restaurant preparation, and another 25 in home usage and disposal. The shocking discovery, at least for supporters of food miles as a gauge of sustainability, was that transportation was the lowest of all factors, accounting for about 11% of overall energy used in that product’s life cycle (Pirog 2001). These findings led several scholars writing in the journal *Environmental Science and Technology* to claim that “although food is transported long distances in general...the GHG [greenhouse gas] emissions associated

with food are dominated by the production phase” (Weber and Matthews 2008).

The shift in thinking, at least on the policy and academic levels, spawned a number of studies that made their way into the mainstream news, thereby providing further counterweight to the extremely popular food miles assessment and, in turn, the basis of the sustainable food movement as a whole. Most notable was a 2006 study to come from New Zealand’s Lincoln University. Led by the researcher Catherine Saunders, the study found that grass-fed lamb shipped from New Zealand to London was four times more energy efficient than grain-fed lamb produced in the English countryside (Barber et al. 2006). What mattered, in essence, was not where the lamb came from but rather how it was produced. This study was soon joined by another much publicized study that discovered how German apple juice imported from Brazil was less energy intensive than apples grown and processed locally. The reason was that apples in Germany were grown largely in hothouses, which are generally very energy intensive, so much so that they countered the 10,000 miles journey from Brazil (Blanke et al. 2005).

Other scholars skeptical of food miles explored the practical dietary implications of locally sourcing food. Considering New York State and the considerable opportunities therein to eat local fruit, Jennifer Wilkins found that, of all the fruit grown in the state, only one – the apple – could feed New Yorkers at a level that met the US Recommended Dietary Allowances. Not only could the other fruits produced in New York not be harvested on a level that would meet basic dietary needs but, as Wilkins noted, New Yorkers would have to forgo eating all tropical fruit, including bananas, a decision that could have deleterious health consequences (Wilkins 2009, p. 174). Other analysts began to wonder about the desirability of scaling down and localizing potentially onerous food processing centers. Writing in the *British Food Journal*, three scholars, wary of the emerging desire to localize food production, noted how “a return to small units within communities may well bring environmental problems such as smell, pollution, waste disposal, visual intrusion, and

nuisance for those communities” (Jones et al. 2004).

Another critique of food miles and the localization that it inspired came through a sociological lens. Writing in the *Journal of Rural Studies*, the sociologist Clare Hinrichs argued that, “making ‘local’ a proxy for the good and ‘global’ a proxy for the bad may overstate the value in proximity” (Hinrichs 2003, pp. 33–45). Central to this line of thought was a growing skepticism that local communities necessarily made more democratic food decisions than regional or global ones. This concern was developed in some depth by Patricia Allen, a scholar at the center for Agroecology and Sustainable Food Systems at UC-Santa Cruz. Analyzing the Santa Monica farmers’ market, she wrote, “The presumption that everyone can participate is a magician’s illusion,” noting how the internecine battles over limited space belied the fabled “fluid cooperation among groups with quite different interests” that farmers’ markets were said to embody (Allen 1999, pp. 120–122).

As some scholars began to question the food miles rubric, others took a more reactionary bent. They began to dismiss local food systems altogether as boutique endeavors of the foodie elite. In turn, they sought to reclaim what they saw as the virtues of the global and industrial food systems: efficiency, accessibility, cost-effectiveness, and high productivity – all qualities necessary for a food system that aimed to feed an expanding global population a healthy diet. Few were more outspoken on this point than the Missouri corn and soy farmer Blake Hurst. In an essay called “The Omnivore’s Delusion,” Hurst argued that expansive supply chains did not undermine the agricultural community. He wrote: “the distance between the farmer and what he grows has certainly increased, but, believe me, if we weren’t closely connected, we wouldn’t still be farming.” He lamented how the sustainable food movement, in its emphasis on localizing the foodshed, offered agricultural prescriptions that “ignore the ‘industrial’ farmer’s experience and knowledge,” much less the impending population explosion that had to be fed. Moreover, he added, most so-called industrial farmers were family farmers (Hurst 2009).

Hurst was joined by Pierre Desrochers and Hiroko Shimizu, authors of *The Locavore's Dilemma: In Praise of the 10,000-Mile Diet* (2012). In an acerbic tone highlighting precisely how politicized the food miles debate had become, the authors wrote that the quest for local and sustainable food “is essentially a fad promoted by bicoastal urban ‘agri-intellectuals’ whose knowledge of and practical experience with food production are typically limited to the world of hobby gardening and a once-in-a-lifetime foray into hunting or killing a backyard animal” (Desrochers and Shimizu 2012, p. 9). In an interview with *Reason* magazine, Desrochers wondered, “If everything was so great when most food was sourced locally centuries ago, why did we go through the trouble of developing a globalized food supply chain in the first place?” More and more critics thought this was an excellent question, one that highlighted a retrograde aspect of the local food movement and its slavish adherence to food miles.

As the science and politics driving the food miles discourse intensified, a related issue intervened to further complicate and polarize the food miles debate. It suggested that, when it comes to sustainable food production and transportation, it's not where our food comes from that matters as much as what it was we ate. The split was between plants and animals. In 2006, the UN's Food and Agriculture Association published a groundbreaking report called *Livestock's Long Shadow*. The report provided a devastating assessment of the environmental impact of eating animal products. It found, most notably, that the global production of meat was responsible for more GHG emissions than transportation. In addition, it documented the extensive impact of animal agriculture on biodiversity loss, land degradation, and water pollution (Desrochers and Shimizu 2012). Subsequent assessments of the correlation between animal agriculture and climate change discovered that *Livestock's Long Shadow* may have understated the impact on GHG emissions. Two former scientists from the World Bank argued that the animal sector may have been responsible for as much as 51% of global GHG emissions (Worldwatch n.d.). The authors of the 51% figure suggested that switching to plant-based calories would “have far more rapid

effects on GHG emissions and their atmospheric concentrations—and thus on the rate the climate is warming—than actions to replace fossil fuels with renewable energy.”

In many respects the debate over sustainable food production and responsible consumer choice began to compare the benefits of eating local versus eating a plant-based diet. According to several studies, the comparison was not even close. After a comprehensive comparison of the two diets – plant-based and local – the authors of a study published in *Environmental Science and Technology* wrote, “we suggest that dietary shift can be a more effective means of lowering an average household's food-related climate footprint than ‘buying local.’ Shifting less than one day per week's worth of calories from red meat and dairy products to chicken, fish, eggs, or a vegetable-based diet achieves more GHG reduction than buying all locally sourced food” (Weber and Matthews 2008). In this context, Rich Pirog now explained, “Food miles are a good measure of how far food has traveled. But they're not a very good measure of the food's environmental impact” (DeWeert 2009).

Currently, an emerging emphasis on veganism as the most ecologically responsible diet coexists uneasily alongside the locavore counterargument that small-scale, locally sourced animal products are ecologically desirable, especially if they come from pasture-raised animals, and even necessary to the future of sustainable food production. On the one hand, the biologist Allan Savory recently (March 2013) delivered an electrifying TED talk in which he argued that rotationally grazing more cattle on global desert land would eliminate the prospect of global warming while simultaneously feeding local populations an abundance of beef. His talk was widely praised (McWilliams 2012). On the other hand, a couple of years earlier, Dr. Richard Oppenlander's book *Comfortably Unaware* argued that all animal production – be it factory farmed or pasture raised – was unsustainable. When it came to the addition of cattle to the landscape, Oppenlander ridiculed the notion, explaining that “greenhouse gas production is 50–60 % higher in grass-fed beef” (Oppenlander 2011, p. 125).

Summary

The future of food miles as a concept central to the evolution of sustainable food systems will remain, for all the criticism it has endured, a sound one. Even if the arguments against food miles – the idea that it's more sustainable to eat a plant-based diet or that globally scaled food economies are ultimately more efficient at feeding the world – are valid, the appeal of reducing food miles will continue to thrive due to the concept's effectiveness as a consumer response to a global food system that is as industrialized and alienating for many consumers as it has ever been in the history of human food production and consumption.

Food Movement

► Food Not Bombs

Food Not Bombs

David Spataro

Department of Earth and Environmental Sciences,
CUNY Graduate Center, New York, NY, USA

Synonyms

Antiwar food justice; Community kitchens; Community meals; Food movement; Food waste and politicized food rescue; Sharing food in public space

Introduction

Food Not Bombs is the umbrella name for a loose network of self-organizing food justice groups that began in Boston in 1980 and whose work is anti-hunger, antiwar, and pro animal rights. Currently the movement is made up of a decentralized network of 500 chapters in 60 countries (Food Not Bombs 2012). Food Not Bombs groups rescue food from various nodes in the food system including farms, restaurants, grocery stores, distributors, community-supported agriculture, and bakeries among many other places. Operating outside of the state, not-for-profit, and religious social service sector, Food Not Bombs food rescue efforts involve local connections with food businesses. These connections create mutually beneficial relationships whereby the businesses can reduce their food waste through regular donations. Once rescued, Food Not Bombs cooks vegan and/or vegetarian meals in shared kitchens and then serves the food in well-trafficked public spaces like parks and plazas. These community meals often feature nonsectarian political literature on poverty, hunger, animal rights, and the US military budget. In addition to regular meals, Food

Not Bombs groups also engage in food solidarity projects: cooking food for demonstrations, fundraisers, conferences and/or meetings organized according to nonviolent social justice principles.

What is called Food Not Bombs is not a single, centrally run organization with a president, officers, board of directors, or staff. Rather, Food Not Bombs has a philosophical foundation in anarchism and direct democracy, a foundation that shuns hierarchical systems. In practice, any one Food Not Bombs chapter tends to be ideologically heterogeneous rather than entirely made up of anarchists. However, the overall texture of the group would be considered what Day (2005) calls “anarchistic.” As such, Food Not Bombs is really a collection of guiding principles and organizational tools that encourage people to create their own local chapter while using horizontal organizational modes. In the same grassroots spirit of the Do It Yourself (DIY) and punk movements, people concerned with the issues of food waste, hunger, and militarization can claim the Food Not Bombs tools for their own communities and create an autonomous local chapter (Holtzman et al. 2007). This model emphasizes that one need not ask for permission – from a Food Not Bombs “leader” or from local politicians – in order to act ethically in the creation of community food security.

Food Not Bombs claims more than 500 chapters on their website, although the decentralized and all-volunteer nature of the movement means that new chapters are emerging while old ones may dissolve or temporarily scale back their work. Measurements of the size of the movement should be understood to be estimates rather than precise statistics. However, the group’s impact can be gauged by examining the longevity of the movement, the growth of new chapters, and the increasing attention – both in favor and in opposition to Food Not Bombs – paid by journalists, academics, and municipalities. Several chapters, for example, have been in the mainstream press and scholarly literature in the late 2000s. This is primarily due to cities adopting copycat legislation that criminalizes sharing food with poor people in public spaces, which has led to arrests of Food Not Bombs activists (see The National

Coalition for the Homeless and The National Law Center on Homelessness and Poverty 2010; Mitchell and Heynen 2009).

Origins and Growth of the Movement

Food Not Bombs originated in the dissolution of the antinuclear movement in the US northeast. Beginning in the latter half of the 1970s, the antinuke movement spanned from the end of the New Left social movements into the early 1980s. As a direct forebear, the antinuke movement's tactics, organizational form, and philosophy are all essential for understanding Food Not Bombs. Antinuke activists blended anarchist, radical pacifist, and Quaker political philosophies. Chief among these ideas was the notion that individuals need not wait to act on their ethical principles, nor act only in the arena of representative electoral politics (see Tracy (1996) for the radical pacifist roots to these ideas). Working in this tradition the antinuke activists occupied and blockaded construction sites and research facilities using nonviolent direct action. Additionally, these more spectacular confrontational actions were based in quotidian forms of action such as prefiguration, consensus decision-making and affinity groups (Epstein 1991; Cornell 2010). Prefiguration is the name given to tactics that create in the present moment the world that people are struggling to create. Thus, the struggle for equality and direct democracy requires that groups eliminate hierarchies and oppressive processes in their organizations and in their everyday lives. For antinuke activists, making decisions horizontally (rather than hierarchically) and working in small groups with strong interpersonal bonds were two central methods of prefiguration.

As the antinuke movement waned, Boston-based activists began to blend political theater with serving food in public space into an innovative form of social protest. Two actions in 1981 in the ongoing campaign against the Seabrook Nuclear Power Plant in New Hampshire foreshadowed the first Food Not Bombs. Both actions involved food and public space and both

contained the seeds of what later became the mature Food Not Bombs model.

At one action, organizers used political theater to protest a Boston bank that had investments in the nuclear arms industry. They created a depression-era soup-line, as if to say that the bank's investments were leading to social crisis on par with the depression. They brought soup and bread out to the sidewalk near the bank and invited all to join, including individuals in nearby shelters (Parson 2010). At the other event, the same group held a bake sale for the legal fund of an arrested friend. Like the soup-line protest, they used a bit of theater alongside their food to impute a political message into the event. Wanting passersby to envision a world where the military, not schools, faced budget shortfalls, they dressed up as members of the military attempting to sell baked goods (Parson 2010). Throughout this period they used political messaging that argued for basic goods such as food and schools instead of war, messaging which they distilled into the very simple and clear demand to "drop food not bombs." Hence the name Food Not Bombs.

As the group of Boston antinuke activists created what would become the first Food Not Bombs chapter, they continued to use many organizational elements of the antinuke struggle. They lived together and organized in an affinity group fashion using consensus for making decisions. Their public meals continued the tactical legacy of nonviolent direct action. Sharing food in public space is much less risky than some of the more famous direct actions of the civil rights and antiwar era – prison hunger strikes, lunch counter sit ins, ship blockades, construction site occupations – but the principles remain the same. The Food Not Bombs public meal embodies the ethos that individuals do not need to wait for the state to take action and create community solidarity; it can be and is done in the here and now by regular people.

Early on, Food Not Bombs in Boston provided food solidarity at a series of demonstrations while also making regular food deliveries to daycare centers, housing projects, and women's shelters. Members of the Boston chapter provided food at the mass rally for disarmament in June 1982 that

was held in Central Park in New York City (Butler and McHenry 2000).

Starting in the late 1980s, differences between municipal policies and the Food Not Bombs philosophy lead to high-profile conflicts between police and activists. In San Francisco, Food Not Bombs activists found that their model for eliminating food waste, hunger, and militarism came up against the interests of the mayor and the Cole Valley Improvement District, a business improvement district (BID) in the city's famous Haight-Ashbury neighborhood. The ensuing arrests, which numbered over 1,000 from 1988 to 1996, were often for violations such as sharing food without a permit (Parson 2010).

While most of the arrests during this period were for violations of health codes, Food Not Bombs continued to conduct their direct action community meals while forging alliances with homeless people and their advocates (Parson 2010). Scholars identify this period in urban policy as one dominated by "quality of life" campaigns. Based upon research that argued that urban disorder is a precursor to more serious crime (see, e.g., Kelling and Wilson 1982), mayors such as New York City's Rudolph Giuliani put emphasis on stopping smaller scoff-laws such as "squeegee men," transit turnstile hoppers, and graffiti writers as well as homeless people who slept, drank, and urinated in public (see Clines 1993). Although Giuliani is perhaps the most well known for these policies, San Francisco's Matrix program began simultaneously to Giuliani's election. Under the Matrix program, the San Francisco police began to cite people for quality of life violations and to push homeless people out of public spaces. Scholars such as Mitchell (2003) argue that this use of the penal system is misguided because it ascribes criminal activity to the actions that poor and homeless people often must take in public space precisely because they do not have private resources. Since Food Not Bombs fed all people and especially the same poor people that the Matrix program sought to displace, activists and their supporters argued that the health codes were being used as an indirect tool for political purposes. Using police to prevent a community meal

thereby reaffirmed one of the guiding principles of the group's direct action food sharing: to make visible food insecurity rather than disguising hunger and poverty (Parson 2010; Mitchell and Heynen 2009).

The criminalization of Food Not Bombs activists has continued along two fronts. First, as Food Not Bombs has spread in the aftermath of the San Francisco arrests, chapters have become nodes in the local networks of alter-globalization activists. Perhaps most widely known for their participation in the 1999 protests against the World Trade Organization (WTO) in Seattle, alter-globalization activists organized opposition at numerous summits of global leaders during the 2000s. Food Not Bombs' connection to these actions has led to state surveillance and repression. This has been particularly the case in the years following 9/11, where the US state has consistently treated radical social movements as either terrorists or potential terrorists (see Heynen 2010). Secondly, as economic inequality in the United States has only grown over the past two decades, cities have continued to use displacement as their main tool for dealing with the families hit hardest by economic crisis. Food Not Bombs' uncompromising commitment to rescuing food and sharing nutritious meals in highly visible public places has led to more disputes with municipal governments and business improvement districts. In the late 2000s several municipalities passed legislation that directly led to the arrests of Food Not Bombs volunteers, a process that geographers Michell and Heynen call "criminalization of intervention" (Mitchell and Heynen 2009).

The major impetus for Food Not Bombs' actions are the abundance of food that needs rescuing, the proliferation of hunger and poverty, and the use of social wealth for producing weapons and engaging in warfare. Neither the actions of Food Not Bombs activists nor the policies of governments have ended these social dynamics. While the criminalization of the movement seeks to channel action into more socially accepted arenas, it has not been successful in changing the course of the movement. These social factors point to the continued presence of Food Not Bombs' direct action community meals in public spaces.

Issues Raised by the Food Not Bombs Movement

The Food Not Bombs movement raises several issues. The most prominent issue is the coexistence in the United States of individuals in need of food alongside system-wide food waste. According to the US Department of Agriculture (USDA), 17.2 million or 14.5% of US households experienced food insecurity sometime during the year in 2010. When disaggregated, the data reveal that households of color are disproportionately food insecure, with 25.1% of black households and 26.2% of Hispanic households experiencing food insecurity during 2010. And because access to food is mediated by having money, one third of households with incomes below 185% of the federal poverty line experience food insecurity (Coleman-Jensen et al. 2011). Additionally the National Resources Defense Council (NRDC) reports that 40% of food in the United States in 2011 went to waste, making wasted food the largest component of solid waste and contributing to greenhouse gas emissions from landfills (Gunders 2012). The NRDC report demonstrates unequivocally that there is an abundance of food produced alongside the existence of US households experiencing lack. Despite the common sense notion that food shortages are immanent threats due to population growth – a kind of persistent Malthusianism – abundance alongside hunger points to issues of distribution rather than production as the root cause of the problem.

Food Not Bombs activists engage in a form of grassroots direct action against this dual problem of abundance and lack. In cities throughout North America, Food Not Bombs volunteers rescue food that would otherwise be going to landfills from many points in the food system. From restaurants, bakeries, farms, distribution centers, and grocery stores, Food Not Bombs volunteers quite literally work with the food that makes up that 40%, albeit a very small portion of it. Additionally, they combine this embodied knowledge with a criticism of the amount of social wealth that is used for various military expenditures versus social welfare programs. Food Not Bombs activists eschew politically neutral explanations for systematic food

waste and budgets overwhelmingly skewed towards militarism. With the public meals they attempt to create a space where people can engage in dialogues that go against the naturalization of these phenomena. During the neoliberal era, policymakers stress that the self-regulating market, as opposed to governments or collective solidarity, is the best mechanism for dealing with social problems. The anti-capitalist principles that provide the foundation for Food Not Bombs contradict this orthodoxy. Under these circumstances, Food Not Bombs remains outside the realm of socially legitimate policy expertise and their work remains largely unknown except in instances where police arrest their volunteers.

Furthermore, the anarchist roots to the Food Not Bombs philosophy reveal issues about the role of the state, nonprofit, and charitable sectors in effectively dealing with these interconnected issues. One of the central outcomes of Food Not Bombs' anarchistic (Day 2005) model is their stance on state and nonprofit charities. The group's principles assert that ordinary citizens motivated by solidarity are the primary agents of social transformation, not governments, religious charities, or nonprofit services. These principles also derive from a criticism of state welfare and charity services (which today are increasingly inseparable) as serving to reproduce the market system and hence reproduce the system that produces the problems rather than eliminate them (see Heynen 2010). While the dominant political discourse debates government services as either fostering dependency (conservative political philosophy) or a temporary safety net for economic turbulence (progressive political philosophy), Food Not Bombs once again takes a different approach. The radical anarchist influence in the movement calls out the social welfare state as engaged in managing fluctuations in the labor market, not in ameliorating the problems that plague US households. These anti-statist philosophies that scaffold the movement sometimes overlap with anti-statist libertarian viewpoints. However, Food Not Bombs' collectivist emphasis on social solidarity and agitation to utilize social wealth for households in need have very little to do with individualist libertarianism.

The heart of this issue is an ideological debate between statist and anti-statist policies as a way to reduce hunger and food waste. Yet questions remain about the relationship between grassroots activism and state action. Historically, there are examples of activists taking on the role of direct action service providers – in other words creating services that help their community survive. Some of these projects led to the state taking on that role. Shepard (2007), for example, tells the story of the Housing Committee of the AIDS Coalition to Unleash Power (ACT UP). Facing the state's unwillingness to give homeless people with HIV/AIDS dignified housing, the Housing Committee decided that they would have to house people themselves. In Shepard's analysis, the group's ability to do both direct action protests and direct services established an embodied praxis for their broader demands, which eventually led to state action on the housing issue. Their success at housing one another bolstered, rather than took away from, their goal of state support. Additionally, Heynen's (2009) analysis of the Black Panther Party's free breakfast program suggests that stalled legislation to create federal free breakfast was actually made politically feasible by the success of the BPP's solidarity breakfast program (see Heynen 2009). In both of these cases, the activists demanded a world where all people have access the means of survival. When faced with the ethical dilemma of their community needing resources in order for people to survive, these groups fused service with political action rather than divert resources into either movement building or depoliticized services.

The frames that individuals use to understand social action typically posit a binary between reformist and revolutionary action. Reformist action is an action directed at policy changes within a liberal framework, while revolutionary action is that which is geared towards changing or transforming state power. Mutual aid or direct action services, which are just other names for grassroots forms of community survival, pose challenges to this binary. On the one hand, they eschew typically reformist activities such as lobbying or asking for government permission, while they simultaneously focus on arenas of social life

such as housing or food that are utterly quotidian compared to the grand scale of revolution. Furthermore, state responses to these actions can complicate the issue because the state may step in to perform services precisely in order to undercut the radicalism behind such services (see the discussion of the women's shelter movement in Enke 2003). Scholars of neoliberalism, conversely, argue that the contemporary penchant for cutting government services actively relies on community-scaled action. These scholars argue that activists doing direct services actually promote more cuts than they create the political pressure for increased services (see Herbert 2005) for an examination of community policing in this context). The history of Food Not Bombs does not present a clear case for either of these positions. However, confrontations between Food Not Bombs activists and city authorities suggest that even if they are feeding people, they are not doing it in the manner and/or in the spaces that the state prefers. At the very least, this suggests that the politics of community services, such as who is doing it and in what context, are a factor in how state forces respond to such work.

Furthermore, the criminalization of Food Not Bombs activists in public spaces across the United States brings up the issue of the legitimate uses of public resources. This issue is especially topical in the wake of the occupations of public parks across the United States in fall 2011 under the banner of the Occupy Wall Street movement. Under neoliberal governance, cities strive to control public spaces for the twin purposes of "quality of life" and "security." As a result the role of public parks in social life has transformed. While perhaps public space has never been the truly open space that the image of the Athenian *agora* implies (see, e.g., Mitchell 2003), these trends have increased privatization and decreased access, often through the mechanisms of user fees, public-private partnerships, and laws against basic functions such as sleeping or sharing food. Many scholars note that privatization has led to the exclusion of the most precarious individuals (see Low and Smith 2006). Food Not Bombs activists use a form of direct action to explicitly confront this trend, serving food to all comers in public places. As would

be expected, these gatherings bring together a diverse group of people, including those that the state wishes to exclude.

The disputes that have ensued, from San Francisco to Orlando, while on the surface coded in the discourse of public health, often pit business and real estate interests against this pluralistic vision of public space. At the very core of this is a question of what collective wealth in the form of public parks, plazas, and open spaces should be used for. Real estate and business improvement districts seek to make public space more amenable to their property value and/or retail interests. They argue that broader social good derives from their success and that making public space available to society's marginalized people hinders their success. Food Not Bombs counters this discourse by actively creating radically open public spaces, arguing that spaces created by social wealth should be available to all people.

Yet the mayor of Orlando, for example, called Food Not Bombs activists "food terrorists" during a protracted conflict about the use of Lake Eola Park ("Feeding Resistance" 2011; Jacobson 2011). The mayor's attempt to code community food sharing within the language of criminal behavior suggests the level of friction in these conflicts. While it is obvious that Food Not Bombs activists are not terrorists, it is also self-evident that they push anti-militarization demands and communalist views that are counter to the prevailing social and economic logic. A major challenge to unpacking these conflicts is that both sides strive to frame their positions through unassailable lenses. Municipal politicians and real estate interests argue that it is an issue of sanitation and park usage, while Food Not Bombs activists respond with the moral authority that comes from feeding hungry people and diverting food waste from landfills. If the debate stays at this level, the issues about the political economy of food waste, about inequality, and about the role of public space in private property values do not get addressed. Furthermore, there is a deeply insoluble element to these disputes. If the value of a neighborhood increases by eliminating marginalized people (see Katz (1999) for a discussion of this with regard to New York City's Grand Central

Station), Food Not Bombs groups are not content to live in such an environment. The purpose of their efforts is to transform such social relationships, rather than conform to them.

Summary

Food Not Bombs is a 30-year-old food justice and antiwar social movement based in the principles of nonviolent direct action. Born in the waning years of the US antinuclear movement, Food Not Bombs began in Boston in 1980 as a collective of antinuke activists engaging in local food rescue, sharing the food in solidarity at women's shelters, public housing projects, and political demonstrations. Food Not Bombs developed into a decentralized and nonprofessional network of hundreds of local chapters in cities across the globe. Local chapters rescue food, cook vegetarian or vegan dishes, and then share a free communal meal in well-trafficked public spaces with nonsectarian literature about ending war and using social resources for people's basic needs. Through their nonviolent direct action community meals, Food Not Bombs advocates that communities take action for their basic needs and against the waste of resources for all aspects of war.

Introduction

Judaism is one of the world's oldest religions and has a rich history of ethical approaches to food, eating, and cooking.

Although food and eating serve central roles in nearly all of the world's religions, they hold particularly outsized places in Judaism. The lived practices of many Jewish holidays often center on food practices. The daily routines of Jewish living frequently highlight issues of food, specifically the *kashrut* regulations that proscribe certain foods, types of meals, and their production and preparation methods. Communal and individual approaches to Jewish life in the contemporary world often hinge on the acceptance, rejection, or adaption of food-related practices, ranging from assimilationist attitudes that reject Jewish foodway particularity to traditionalist ones that enforce rigid separation (Greenspoon et al. 2005). Ethical questions regarding the appropriate means of producing, preparing, and eating food – and even what stuffs merit the designation of “food” at all – underlie all these issues.

Kashrut

The ethics of Jewish eating begin (and some might argue, end) with *kashrut*, the Jewish laws of food and eating laid out in the Torah (Pentateuch) – the first five books of the Hebrew Bible and the most important text in Judaism. *Kashrut*, also called the laws of kosher, set out what food Jews may eat; how they may produce, cook, and prepare it; and what the ramifications are for violation of said laws. The basic rules appear in two of the books of the Torah, Leviticus 11 and Deuteronomy 14. Leviticus 11 offers a list of permitted and prohibited foodstuffs. Explicitly permitted are animals that chew their cud and possess split hooves as well as water-dwelling animals with fins and scales, birds that are not explicitly rejected, and various forms of locusts and other related insects. Numerous animals are explicitly rejected, famously including the pig, but the antiquity of the text makes impossible the precise identification of some prohibited animals with

Food Preparation, Cooking, and Ritual in Judaism,
Table 1 Permitted and prohibited foods according to
Leviticus 11

Explicitly permitted	Explicitly rejected
Split-hooved cud chewers	Camel, daman, hare, swine
Water dwellers with fins and scales	Water dwellers without fins and scales
All birds not explicitly prohibited	Eagle, vulture, black vulture, kite, falcon, raven, ostrich, nighthawk, seagull, hawk, little owl, cormorant, great owl, white owl, pelican, bustard, stork, heron, hoopoe, bat
Winged swarming things that walk and leap on four-jointed legs: locusts, grasshoppers, and crickets	All other winged swarming things
(None listed)	Mole, mouse, great lizards, gecko, land crocodile, lizard, sand lizard, chameleon, four legged crawlers, belly crawlers, many-legged swarmers

particular species. As numerous scholars have noted – most especially Mary Douglas – the permitted animals seem to occupy privileged positions within each category of animals (Douglas 2003). Split-hooved cud chewers are paragons of land animals, for example, whereas water dwellers with fins and scales serve as exemplars of water animals (see Table 1 below).

Neither Leviticus nor Deuteronomy provides a clear ethical explanation for the prohibition of eating certain animals as food and the permission to eat other ones. The texts merely indicate that prohibited animals are “unclean,” “impure,” or “defiling.” Yet both Leviticus and Deuteronomy do provide theological rationales. Leviticus 11.43 links unclean animals with unholiness and conversely clean animals with holiness. The next verse explicitly calls for Jews to “be holy for I [God] am holy.” Eating clean animals and avoiding unclean ones therefore becomes a religious obligation, an enacting of holy mimesis. In classical Judaism, one follows these laws because God demands it, and because the rules are part of the ritual complex that defines Judaism. A more

precise ethical basis of these food laws remained to be developed in the postbiblical tradition.

Several other major sets of biblical laws form the basis of kashrut beyond the set of permitted and forbidden animals. Deuteronomy 14.21, Exodus 23.19, and Exodus 34.26 prohibit the cooking of a young goat in its mother’s milk. This statement – believed by Jewish leaders to be especially amplified since it appears three times – became the basis for the probation of mixing dairy and most types of animal flesh in the acts of cooking or eating.

Distinct from the prohibition on eating certain unclean animals, the biblical text provides no theological rationale. But unlike the rather arbitrary list of permitted and prohibited animals of Leviticus and Deuteronomy, the prohibition of cooking a young animal in its mother’s milk conjured a near-universal sense of ethical reprobation, at least in the minds of the ancient rabbis who codified the kosher system. This combined with the prohibition against the consumption of blood-eating in Genesis 9.4 to result in what Talmudist David C. Kraemer calls “an affirmation of life and a repudiation of death” (Kraemer 2008, p. 14). From an ethical standpoint, Judaism recognizes both milk and blood as the stuff of life and meat as the stuff of death. Not only is mixing of the two unholy and inappropriate, but the very consumption of blood (life) raises problematic theological and ethical issues.

As the essence and symbol of life, blood belongs to God, not human beings. To eat it would therefore be to proclaim oneself similar to the divine, an act Judaism identifies as idolatrous. Like other ancient near eastern people, Judaism in antiquity called for blood sacrifices offered to the divine. Yet the Genesis text implies that drinking blood violated not only ritual decorum – since it positioned the drinker as similar to God – but ethical standards as well. The same chapter that prohibits blood drinking also prohibits the spilling of human blood on the grounds that God made humans in God’s own image (Gen 9.6). The Torah here links the drinking of blood with the crime of harming another person and with a form of symbolic deicide. Similarly, it links the avoidance of

drinking blood with respect for the divine image, justice, and profundity (Gen. 9.5-7).

Kosher slaughter and farming regulations provide another avenue for considering the ethics of Jewish eating as rooted in the Torah. Historians of Jewish practice disagree on to what extent these laws were followed during biblical times, but by the Talmudic period (first to fifth centuries C.E.) they had become an object of intense rabbinical interest (Berg 2008). Kosher slaughter, or *shechita*, requires a specific series of actions. First, the slaughterer must be a religious Jew acquainted with the rules of *shechita* as well as observant of the other ritual requirements of Judaism. Second, only an undamaged and extremely sharp blade may be used as the implement of slaughter. The blade must lack any nicks or other irregularities. Finally, *shechita* requires that the butcher kill the animal with a single deep cut across the neck, severing both the trachea and esophagus (Grunfeld 1982).

While debates continue over whether any method of slaughter can truly be ethical, the mainstream Jewish tradition has historically claimed that *shechita* is a less painful and more humane way to slaughter animals. Today, kosher authorities such as the Orthodox Union position *shechita* as an “instantaneous death with no pain to the animal” (Luban 2012). Importantly, the vast majority of traditionalist Jews such as those who operate and support the Orthodox Union follow the laws of *kashrut* out of ritual and spiritual obligation, and not primarily for ethical reasons. Yet the ethical support for *shechita* serves as an explanation for why God requires this form of slaughter, as well as a buttress to explain and defend the logic and practice of kosher slaughter to non-Jews and to liberal Jews more interested in ethical than ritual practices. In the late twentieth century, there emerged a small movement of gentile (non-Jewish) proponents of kosher slaughter, who urged it as an ethical alternative to mainstream factory farming in the United States. On the other hand, a gentile opposition movement to kosher slaughter emerged in Europe, which envisioned kosher slaughter as inferior to scientific slaughter and therefore unethical.

The agricultural laws of the Torah also prescribe a particular ethics of farming. Fields may not contain mixed plantings, and the corners of the fields must be left unharvested so as to provide available food for the poor, travelers, orphans, and widows (Lev 23:22, Deut 24:19). Similar laws required that grapes left on the vine, or olives left on the tree, must be left for such individuals as well (Lev 19:10, Deut 24:21). It is unclear to what extent such laws were actually practiced in ancient times, but throughout the Middle Ages and into Modernity, Jewish agriculturalists did engage in this form of charitable contribution. Today, some Orthodox Jews in Israel continue to consider these laws binding, whereas other Jews opt to follow the spirit rather than the letter of the law, by donating crops to foodbanks.

Talmudic interpretation of the laws of *kashrut* – which subsumes all of these biblical regulations – focus not so much on the ethics of individual practice or universal morality but the notion of proper table fellowship. As Jordan D. Rosenblum has argued, rabbinic interest in food fixated on with whom one could eat (Rosenblum 2010). The appropriate and ethical answer, the rabbis of the Talmud explain, is other Jews who also follow the laws of *kashrut*. To do otherwise would be to tacitly permit idolatry and worship of foreign deities. In the nineteenth and twentieth centuries, liberal Jewish reformers would challenge this approach, also on ethical grounds, arguing that excluding gentiles from table fellowship with Jews was an affront to universal human notions of brotherhood. Yet today many Jews still follow the kosher laws. They are hardly a relic of the past, but a living tradition that provides ritual and ethical guidelines to Jews who consider normative Jewish law (*halacha*) binding.

Praying, Feasting, and Fasting in the Jewish Tradition

Kashrut and its interpretation serve as only the beginning of Jewish views of the ethics of food and eating. Talmudic and later rabbinic interpretations, as well as contemporary lay perspectives and creative changes, have resulted in a variety of

Jewish ethics of food. Jewish perspectives on the ethics encompass mundane eating, festive eating, and fasting. Prayer and other ritual actions are central to all of these. In fact, one cannot separate prayer from ethics within the Jewish context.

Every Jewish meal begins and ends with a ritual blessing. The precise blessing depends on the nature of the meal. Strictly speaking, only sittings including bread merit the proper Jewish designation of “meal” and receive the full ritual of hand washing, *motzi* (the prayer over bread), and grace after meals. The central act in this ritual is the *motzi*, a short prayer that thanks God for bringing forth bread from the Earth. Alternative prayers address God in thanks for bringing forth grains, as well as fruits of the trees (nuts, apples, etc.), earth (vegetables, etc.), vine (wine or grape juice), as well as a “catchall” prayer that thanks God for creating all other foods. Grace after the meal similarly varies depending on the nature of the meal, but like the *motzi* blessings and its variants, these post-eating prayers focus on the nature of thankfulness and the grace of God.

The food prayers of Judaism serve to foster a system of recognizing the divine hand in the creation and production of food. The prayers explicitly thank God for creating the food and causing it to come forth out of the Earth. As historian David C. Kraemer has written of the Jewish tradition of blessing the meal, “eating will no more be a quotidian act but an act that notices the Creator and His design” (Kraemer 2008, p. 75). The tradition recognizes eating as a form of connecting with the divine and of offering thanks to God for having created a world wherein food can grow and nourish people. Judaism also rejects any idea of informal or unintentional eating. All eating becomes marked with prayers, separated from the other daily activities of life. From an ethical perspective, this marks eating as an intentional act. While certainly the tradition does not explicitly proscribe that Jews be mindful of the farmers, laborers, cooks, and others who produce and prepare the food, the prayers do insist that those eating it become aware that it is not them but rather the divine who created the food and therefore their enjoyment of it must be in the context of thankfulness.

Beyond the scope of normal everyday eating, Judaism also features an extensive tradition of festival eating. Religious authorities, texts, and cultural traditions require and suggest particular eating requirements for holidays such as Hanukkah, Sukkoth, Purim, Shavuot, and of course Passover, the most notable food-related holiday of Judaism. The tradition ascribes particular meanings to foods eaten on each holy day, generally linking the foods to the religious meanings associated with the holidays. Rabbinic sources indicate that the miracle of Hanukkah – the holiday commemorating the rededication of the Second Temple after its desecration by Greco-Syrians – was a single batch of oil that lasted over a week. The tradition therefore calls Jews to eat foods rich in oils, generally fried doughnuts or potato pancakes, depending on the regional variant tradition. Similarly, Shavuot – the holiday commemorating the giving of the Torah – is associated with sweet foods based on milk and honey, the biblical foods associated with the land of Israel and the sweetness of the Torah. Again, eating becomes not simply a mundane activity but an intentional act of reconnecting with community, history, and tradition. Eating prescribed foods serves as a symbol of being a Jew and following the tradition of the people and religion.

Nowhere is this more evident than the holiday of Passover (*Pesach*), also called the Festival of Matzo (Unleavened Bread). By its very name, the Festival of Matzo clearly places food at the center of the theological and ritual menu. Passover commemorates the exodus of the ancient Israelites from bondage in Egypt and the culmination of that exodus in the receiving of the Torah at Mt. Sinai. Unleavened bread, or matzo, symbolizes this story because the tradition holds that the exodus was so alacritous that the Israelites had no time to allow their bread to rise. Regardless of the historicity of the exodus events – a matter of some dispute among both academics and many liberal Jews – Passover is one of the most celebrated of all Jewish holidays, even among secular and liberal Jews. Some scholars have noted that the holiday’s association with food may explain part of that popularity (Weissman 1994, pp. 219–263).

The central ritual of the Festival of Matzo is the removal of prohibited grain and grain products (*chametz*) from the home and the abstaining from all grain products other than matzo and its derivatives throughout the weeklong festival (7 days in Israel and among some in the diasporic Reform Jewish community, 8 days otherwise). Like other forms of Jewish eating, Passover transforms eating into an intentional act that connects one to the community and to God. Throughout Passover, Jews must be especially observant of their eating so as to avoid eating or even benefiting from any use of *chametz* – generally defined as foods derived from one of the five prohibited grains: wheat, rye, spelt, barley, and oats. Jews of Central European ancestry also avoid *kitniyot*, various other grains, and legumes similar to *chametz*. Numerous variants exist, but all Jews agree that the essential ritual observance of Passover is the avoidance of these prohibited foods and the intentional eating of matzo, especially through the ritual retelling of the story of the holiday in the Passover Seder.

The Seder not only amplifies the intentional eating found throughout Passover and all Jewish eating but adds to it an ethical obligation to welcome the stranger to the table and retell the story of freedom from bondage. While it has undergone many transformations over the centuries, the Seder is a ritual meal wherein Jewish families recount the narrative of Passover making use of symbolic foods. Matzo represents the “bread of affliction” and the need to flee from slavery. Other foods such as green herbs and eggs represent the resiliency of life and new beginnings, respectively. Since the middle ages, an ornamental platter called the Seder plate holds these foods and serves as ritual focus of the meal (Cooper 1993, pp. 113–115).

In what is generally recognized as one of the oldest prayers of the Seder, the *Ha Lachma*, the participants of the Seder ritually invoke the narrative of Jewish people as well as situate the Seder as an event intended to convey an ethical teaching and not merely a historical one:

This is the bread of affliction that our fathers ate in the land of Egypt. Whoever is hungry, let him come and eat; whoever is in need, let him come and join in

celebrating the Pesach festival. This year we are here, next year may we be in the land of Israel. This year, slaves, next year – free men. (Elias 2000, pp. 53–55)

The ethical position of the *Ha Lachma* is obvious. Matzo is not merely a bread product but a symbol of slavery and freedom. All who want to eat and observe the festival – debate exists within the tradition of whether this applies only to Jews or any hungry person – are invited to attend the Seder and eat and observe. As numerous Jewish commentators have remarked, this prayer and those like it in the service transform the Seder from merely a meal to a pedagogical device intended to teach the necessity of remembrance, gratitude, feeding the hungry, and empathy for the enslaved (Elias 2000, pp. 52–56).

While feasting may attract far more interest than its inverse, the Jewish fasting tradition is as well developed within the religion as is the festive eating tradition. Judaism identifies six major fast days, the most notable of which are Yom Kippur (the Day of Atonement) and Tisha B’Av (the ninth of Av, commemorating the destruction of the temples). The reasons for fasting vary by the observance, but generally they fall within one of two categories: repentance and commemoration.

The fast of Yom Kippur represents the most important fast of the Jewish calendar, and most Jews identify Yom Kippur itself as the most important and sacred of all Jewish holidays. Tradition indicates that on Yom Kippur, God issues his final decree as to the fate of all living beings over the coming year. It is a solemn day, filled with prayers and commemoration of those who have died. The Torah identifies the fast of Yom Kippur as one of repentance (Lev 16, Lev 23.26–32) and calls for the Jewish people to afflict themselves and seek forgiveness from God. Refraining from eating therefore becomes a symbol of bodily restraint as well as self-control. While a quasi-magical reading of the fast would see it as an invocation meant to spur divine favor and forgiveness, the tradition understands the fast as a means by which one seeks to purify and purge oneself. In recent decades, contemporary Jews have also reinterpreted the fast as offering an opportunity to empathize with the hungry and

have organized food drives and other social justice events oriented around alleviating hunger.

The Tisha B'Av fast by contrast is one of remembrance, as are several of the more minor ones. Here fasting does not symbolize a request for forgiveness but an identification with Jews of past generations and forging of communal ties across generations, time, and distance. Tisha B'Av commemorates the destruction of the First and Second Temples in 586 BCE and 70 CE, respectively. (The tradition ascribes other remembrances to this day as well, though these are the most notable.) Though reasons for the fast vary among commentators, most understand the fast as a form of asceticism meant to recognize the loss of the temples. Fasting thus becomes a form of ritualized mourning for the destruction of tradition, life, and ritual observance engendered by the loss of the temples.

Contemporary Challenges and Alternative to Kashrut

While the laws of kashrut have been fixed for over a millennium in the Talmud and its interpretations within the Jewish legal corpus (halacha), those perspectives are not the terminus of Jewish ethical interpretation of kashrut. Today, progressive or liberal Jews look to vegetarian kashrut and eco-kashrut as contemporary options for Jewish ethics of eating. This is especially true among “post-halachic Jews”: those who take the religious position that the traditional legal and ritual norms of Judaism must change in modern societies. In North America, these groups are primarily found among Jews associated with the Reform, Reconstructionist, and Renewal movements, as well as some secular Jews. More globally, such Jews often identify themselves as adherents of liberal or progressive Judaism.

Historically, Jewish thinkers have compared kashrut to vegetarianism. The Torah describes the Edenic paradise as vegetarian, and Genesis implies that meat eating was granted by God only belatedly. Supporters of “vegetarian kashrut” can point to statements by such respected thinkers as Rashi (1040–1105), Maimonides (1135–1204),

and Nachmanides (1194–1270) as indicating that God’s original intention had been for humans to eat a vegetarian diet. In more recent time, Rav Kook (1865–1935), the first Ashkenazi chief rabbi of Israel during the early twentieth century, argued that the kosher laws functioned to lead Judaism slowly back toward vegetarianism, a position that today many proponents of vegetarian kashrut accept (Schwartz 2001, p. 3).

At its heart, vegetarian kashrut envisions the kosher system as a foundation on which to build an entire edifice of Jewish vegetarianism. Following Rav Kook, proponents argue that kashrut in its traditional halachic form existed only as a tool to wean Jews away from meat and toward a more intentional form of eating. Vegetarian kashrut supporters note that kosher laws limit only the production, preparation, and consumption of animal flesh. They look to vegetarianism as the divinely intended goal of the kosher system and envision a Jewish food ethic that puts animal rights, animal welfare, and the human relationship with nature at the center of the religion’s moral compass.

Other contemporary Jews have formulated a movement known as “eco-kosher” as an alternative to traditional kashrut. Eco-kosher focuses on the means of production far more than the material consumed, unlike either halachic kashrut or vegetarian kashrut. Rabbi Zalman Shacter-Shalomi, the leading light of the American Jewish Renewal movement, coined the term in the late 1970s. Rav Zalman and other proponents of eco-kosher have offered multiple formulations of the meaning of the term, but all focus on the sustainable and just production of food that does as little damage as possible to the Earth’s ecosystem, treats agricultural workers with dignity, and minimizes the suffering of animals.

Zalman intended eco-kosher as an evolution that encompassed halachic kosher, meaning that he insisted on following the traditional kosher laws in addition to the new eco-kosher principles. Other proponents of eco-kosher envision it as an alternative or even replacement of traditional kashrut. The American Reform movement’s recent publication on the ethics of Jewish eating (*The Sacred Table: Creating a Jewish Food Ethic*) presents eco-kosher in this way: offering it as one

option in a “buffet of educated choices” that include halachic kashrut, vegetarian kashrut, environmentally focused kashrut, social justice-oriented kashrut, and feminist kashrut. What unites all of these forms of Jewish eating is the idea of intentionality, ethical eating, and a proclaimed continuity with tradition alongside innovation – though more traditional critics would assail them on that last point (Zamore 2011).

Proponents of traditional kashrut have also created a kosher variant that, in their own words, “bring the Jewish commitment to ethics and social justice directly into the marketplace and the home.” Appropriating the traditional *hekhsher* or certification mark that a kosher supervisor places on an approved kosher food, the Magen Tzedek Commission had created a set of ethical standards including animal welfare, corporate integrity, fair wages for agricultural workers and other employees, and rights to collective bargaining. Importantly, Magen Tzedek considers only food already certified as kosher as eligible for its own ethical kosher certification. It therefore assumes halachic kashrut as its foundation and extends its ethical consideration from there (Magen Tzedek 2012).

The Orthodox Jewish community has also had to respond to ethical lapses in the kosher agricultural industry. The most notable case relates to Agriprocessors, the United States’ largest kosher slaughterhouse, which was raided by immigration officials in May 2008. Government investigators discovered that not only was Agriprocessors employing nearly four hundred undocumented immigrants but that between thirty and sixty were children, many of whom worked in difficult and dangerous positions. The managers of the plant, all Orthodox Jews, faced dozens of labor and fraud charges in state and federal jurisdictions. One manager fled to Israel to escape prosecution. The fallout shook the Jewish community, with kosher-observant Jews debating what they expected from kosher-certified industrial scale agribusinesses, a discussion that remained ongoing nearly a decade later (Rubel 2012).

Finally, just as Jews who accept kashrut in either its traditional halachic form or a newer

alternative form can claim an ethical foundation to their practices, so too can Jews who reject kashrut. At its heart, the kosher laws function to create a separate Jewish community and establish boundaries of what counts as food, how one eats it, and with whom one can eat. Many secular or nonpracticing Jews reject kashrut on precisely those grounds: that it creates a separation between Jew and gentile and therefore is an unethical form of prejudice. David Kraemer characterizes such choices as “motivated by the desire to remove boundaries between Jews and their Christian neighbors. . . [and] motivated by the opinion that all humans are God’s creatures, all members of a single human race” (Kraemer 2008, p. 138).

Judaism’s ethical approaches to food and eating are extremely varied (Marks 2010). While rooted in the Torah and Talmud and developed throughout Jewish law and tradition, Jewish food ethics are quite diverse. Yet all approaches to Jewish eating emphasize the centrality of ethical and religious choices in the act of producing, preparing, eating, or abstaining from food. Far from a quotidian act, the Jewish tradition transforms eating into a central practice with far-reaching implications.

Conclusion

Food ethics serve an important role in Judaism. The kosher system (kashrut) serves as its basis, delineating which foods are or are not appropriate to eat. The tradition identifies the act of following the kosher laws as ethical and holy, and as creating a holy community that follows divine mandate. Praying, feasting, and fasting cement food ethics in the daily lives and yearly liturgical lives of Jews. All food is blessed, making eating a sacred act in itself. Holiday feasting and fasting amplify this sense of intentional eating. In contemporary times, a variety of alternative systems of Jewish food ethics have developed. Eco-kashrut and vegetarian kashrut serve as two examples, as do Jewish groups that reject the kosher system on ethical grounds. Jewish food ethics are quite varied, but all identify eating as an act of ethical value and not just nourishment.

Introduction

The retailing of food refers specifically to the marketing and sale of food items, both processed and fresh, from a retailing outlet. This retail outlet in North America and within an increasingly global context takes the form of a grocery store. In addition to food and food-related items, grocery outlets are increasingly beginning to offer a

diverse range of products from pharmaceuticals and home goods, to furniture, clothing, and banking services. As cities and the populous' grew further away from agricultural sites, there was an increasing dependence on food retailing outlets for one's food procurement. While there are other models of food retailing such as Community Supported Agriculture (CSA) and farmer's market models, this entry will refer specifically to those brick-and-mortar outlets that are privately or publicly managed companies. In Canada, the food retailing scene is dominated by just three major retailers: Loblaw Company Limited, Sobeys Inc., and Metro Richelieu, with Loblaw Company Limited far outpacing the other retailers. Within the Canadian and American contexts, there is a considerable concentration of power at the retailing level. As such, oligopolistic supermarkets and their wildly successful own-brands have reconfigured the food supply chain and have emerged as powerful authorities on what is sold and thus consumed. This entry will explore large corporate food retailers and the problematic nature of corporatized food sales, preceded by analysis of food retailing brands, including private label own-brands. While this entry draws largely from material in the Canadian context, similar food retailing models exist in the USA and increasingly in developing nations across the globe with the emergence of transnational corporations (TNCs) infiltrating global food sales.

Historical Significance Product Differentiation

Before the establishment of many of the modern governmental departments, much of the legislation governing food was based on antiadulteration laws to protect consumers from economic fraud (Ostry 2006; Winson 2013). Canada's *Adulteration Act of 1874* was applied nationally by 1919 and was modeled after Britain's *Adulteration of Food and Drugs Act of 1872* following a sanitary revolution centered on food supply contamination (Ostry 2006; Winson 2013). A similar trend toward antiadulteration legislation occurred in

the USA with the 1906 drafting of *The Pure Food Law* following public outrage from Upton Sinclair's book *The Jungle* that outlined the grotesque conditions of beef slaughterhouses (Ostry 2006; Winson 2013). Winson (2013) contends that this form of antiadulteration regulation set the groundwork for processors to engage in branding their own products and promoting product differentiation. Ostry (2006) also notes this shift to standardized production with the *1907 Meat and Canned Food Act* that established a regulatory system for the content, weight, and name of the producing company for canned meat goods alongside the expansion of processing industries and retail chains.

The responsibility of overseeing national nutrition shifted to the Department of Health following the implementation of the *Food and Drug Act* in 1920. Of notable importance here is that this act distinguished between *adulterations* and *misbranding*, following the discovery of micronutrients and the resultant vitamin mania (Ostry 2006). This definitional distinction is emblematic of the shift toward advertising, marketing, and health-based claims tied to food products as well as quality control and the grading of products (Ostry 2006). Even in the infant stages of such change toward regulatory standardization alongside product differentiation, adding value to one's products served as a profitable way to shape the food environment. Much like the shift to regulatory standardization of the 1920s, the current food environment has been further embedded in processes of standardization. Branding and differentiation were key historical moments within food retailing and is being exercised by today's food retailing powerhouses.

The Big Three: Current National Retailers in Canada

The Loblaw Company Ltd. is a national company that operates under a number of store banners and brands. In Ontario specifically, Loblaw has stores under the following names: No Frills, Real Canadian Superstore, Wholesale Club, Shoppers Drug Mart, T&T Supermarket, Fortinos, Valu-Mart,

Independent, Zehrs Markets, and Loblaw's outlets (Loblaw Company Limited 2015). The banners Provigo, Atlantic Superstore, SaveEasy, and Maxi are found outside Ontario (Loblaw Company Limited 2015). At these outlets, a number of private label brands can be found, which include: President's Choice (PC), No Name, Life Brand, and, in those stores that have included diversified retailing, Joe Fresh clothing and makeup, and President's Choice (PC) Financial (Loblaw Company Limited 2015). The largely successful PC home-brand also has a number of spin-offs for a wide range of consumers: PC Organics, PC Blue Menu (reduced fat/sodium), PC Black Label (gourmet and artisanal goods), PC Green (environmentally responsible cleaning and household goods), and PC Free From (meat free from additives), to name a few (MacDonald 2016).

Sobeys Inc. subsidiary stores, while smaller in scale, nationally, than Loblaw, is still a major national food retailer in Canada. Sobeys Inc. is owned by Empire Company Limited – a Nova Scotia-based corporation whose main businesses are food retail and a real estate investment trust (Empire Company Limited 2014). Similarly to Loblaw, Sobeys Inc. is a national company that carries a number of banner stores and store-specific brands. Sobeys Inc. operates under: IGA, IGA Extra, Safeway, Thrifty Foods, Foodland Co-op, FreshCo., Price Chopper, Lawton's Drugs, and Sobeys stores. A number of private label brands are operationalized at Sobeys Inc. banner stores, which include: Compliments and S!gnal. Like the Loblaw PC brand, there are a number of Compliments streams: Compliments Balance (dietician-verified foods), Compliments Gluten-Free; Compliments Organic, Compliments Greencare (environmentally friendly household products), and Sensations by Compliments (premium foods). S!gnal is akin to the Loblaw No Name brand, where a low price and simplistic, value-centered branding is underscored (MacDonald 2016).

The third major Canadian retailer is Metro Inc. Like Loblaw, Metro Richelieu offers both food retailing and pharmaceutical banners. These banners include: Metro, Metro Plus, Super C, Marché Extra, Marché AMI, Les 5 Saisons,

Marché Richelieu, and Food Basics for food, and Brunet, Clini Plus, Pharmacy, and Drug Basics for pharmaceutical needs (Metro Richelieu Inc. 2015). Brands include Irresistibles and Selection. Similarly, each of these brands is streamed to specific niches: Irresistibles Gluten-Free, Irresistibles Organic, Irresistibles LifeSmart, and Selection Eco (Metro Richelieu Inc. 2015). Metro Inc. is represented in Ontario and Quebec, where the majority of banner stores are located.

Western Canada also has the Overwaitea Food Group (OFG) as central food retailer. The current manifestation of OFG began in 1915 in New Westminster, British Columbia (MacLachlan 2001; The Jim Pattison Group 2016). OFG is a subsidiary of the Jim Pattison Group and operates under the following banners: Save-On-Foods, Overwaitea Foods, PriceSmart Foods, Cooper's Foods, Urban Fare, and Buckley Valley Wholesale (Overwaitea Food Group 2016). The Jim Pattison Group is a holding company, based in Vancouver, British Columbia, with reported annual sales of \$8.4 billion (The Jim Pattison Group 2016). With over 39,000 employees, the group is the second largest private company in Canada (The Jim Pattison Group 2016). The Jim Pattison Group took ownership of OFG in 1968 and have since added a range of other food-related companies, such as the fishing company Canfisco, and Ocean's seafood products (The Jim Pattison Group 2016). The group also owns complementary companies related to food production such as Peterbilt transport haulers and agricultural farm equipment, including John Deere sales (The Jim Pattison Group 2016). Future research into whether the Overwaitea Foods Group's plans to future penetrate eastern Canada's food retailing scene is warranted given the massive capital reach of this retailer.

Another intriguing consideration in the tightly consolidated retail race is the inclusion of point-based reward programs as an added incentive for shoppers to choose one retailing location over another (MacDonald 2016). However, the potential for rewards programs to encourage the consumption of particular items over others is problematic as Nestle (2007) notes that any encouragement to *eat more* in a compromised

food environment can impact diet. This situation is further complicated with many retailers offering health-based dietary advice and rewards programs amidst their own-branded goods.

Branded Goods and Own-Brands

In Canada, a lack of competition has resulted in increasingly consolidated corporate food empires that have become historically entrenched within the Canadian foodscape (Winson 1993). One such company includes the George Weston Company, whose then-president, W. Garfield Weston, took controlling interest of Loblaw Company Ltd. in the early 1950s, following a large purchase of Loblaw stock from cofounder J. Milton Cork (Loblaw Company Ltd 2011). Such oligopolistic expansion was largely facilitated by the emergence of branded goods and the appearance of a higher proportion of processed foods in grocery stores. In terms of the corporate concentration of the Canadian retailing scene, there are few notable developments that need to be outlined; these include the rise of supermarket power, the boom of private label own-brands (Winson 1993; Burch and Lawrence 2007), and economies of scale for food manufacturing inputs.

In regards to supermarkets as key powers within the modern food system, there is literature on the proposed shift within the agro-food commodity supply chain from one that is a *producer-driven commodity chain* (PDCC) to one that is a *buyer-driven commodity chain* (BDCC). Here, a producer-driven chain is one in which transnational manufacturers are the primary actors within the supply chain, whereas retailers are the primary actors within a buyer-driven chain (Konefal et al. 2005). Konefal et al. (2005) have noted the shift from producer-driven global commodity chains with transnational manufacturers as the primary actors to retailers within buyer-driven commodity chains through further consolidation and concentration resulting in global oligopolies (Winson 1993; Konefal et al. 2005).

Oligopolistic supermarkets and the wildly successful corporate brands they control have reconfigured the supply chain as transnational

supermarket chains (TSCs) (Konefal et al. 2005) through the multitude of markedly differentiated and innovative products, often produced at a high-quality standard (Burch and Lawrence 2007), while reducing transaction costs. The successful implementation of value-added processing within producer-driven commodity chains as purported by big brands has served as a model for retailers to implement their own versions of branded goods, but within a new food environment. Through circumventing retail price management, which historically allowed food manufacturers to set the prices at which goods were sold (Burch and Lawrence 2007), supermarkets engaged in horizontal coordination and integration (as in the expansion into clothing, pharmacy, garden retail), as a way to mitigate risk through product diversification, as well as maximize on consumer spending. This has been facilitated by excess production and economies of scale in production but also mass consumption (Konefal et al. 2005). Noting the consumer success of brand establishment, as well as emphasis on price (Smithers et al. 2008), supermarkets have maximized on the model initially established through producer-driven commodity chains.

Unlike their branded counterparts which require extensive advertising to develop consumer brand awareness, home-brands offer a similar product as offered by a big brand but often at a markedly lower price. Similarly, home-brands tend to offer high-quality and often innovative products, as they are not bound by the same long-term consumer targeting as branded goods. Loblaw Company Ltd. was one of the first to introduce home-brand items. For example, following the launch of their President's Choice (PC) line in 1984 (Loblaw Company Limited 2011), Loblaw spearheaded nutritional labeling for all PC products in 1994 – 10 years prior to the legislative requirement for all packaged food products to carry nutritional information labels in 2004 (Loblaw Company Limited 2011).

Own-brands also carry exclusivity. Unlike branded goods, which can be retailed in a number of places, and which is the aim of branding, own-brands are tied exclusively to the purveying retailer (Fitzell 1992). PC is only sold in Loblaw

Company Ltd. banner stores. Interestingly, own-brands have been so successful they have essentially developed their own form of branding. The generic, simplistic appearance of a bright yellow No Name product has very much developed into a form of recognizable branding (Fitzell 1992).

Merchants of Nutritional Advice

In Loblaw banner food stores, the Guiding Stars program provides a visual rating system for foods to allow for healthful and easy food choices. The Guiding Stars system is based on Health Canada's Canada Food Guide dietary information, in conjunction with the Canadian Food Inspection Agency (CFIA). The system ranks foods from one-star to three-stars based on one of the following four algorithms: general food and beverage, meats/poultry/seafood/nuts, infant/toddler foods, and fats/oils. More simply, Guiding Stars is based on a credit/debit system. A product is credited if it contains vitamins/minerals, dietary fiber, whole grains, omega-3 fatty acids; and a product is debited if it contains saturated or trans fats or added sodium and added sugar (Guiding Stars 2015). Therefore, an item with three-stars would have more credits. An item can also receive no stars if the product is new and has not yet been assessed or if the product has 5 or fewer calories (Guiding Stars 2015). Products may also receive no stars if it does not meet nutritional standards, with the reminder that "Of course, you can still enjoy these foods. Nobody is expected to eat star worthy foods all the time" (Guiding Stars 2015). Provided the profitability of many value-added items, it is not surprising that, despite the push to appear healthful, retailers are also promoting the notion of indulgence.

In a similar vein to Loblaw Company Ltd.'s Guiding Stars Program is the My Healthy Plate Program. Here, rather than stars, food items are rated using a smiley-face icon. The bigger the smile, the better and more healthful the item is deemed to be. A "great choice" has "more" protein, fiber, vitamins/minerals, whole grains, and fruits and vegetables and "less" fat, saturated fats,

sodium, and sugar (Metro Richelieu Inc. 2015). Similar again to the Guiding Stars program is the vagueness of the program's criteria, alongside the reconfiguration of portion sizes. Under this program, products like ice cream (provided there is less than 10 g of fat or less) and frozen French fries (provided a serving has 4 g of fat or less) are a "good choice" (Metro Richelieu Inc. 2015). There is no poor choice face in the program, but there are items that will not have any face, either because it is a new product that has not been verified yet or it does not meet the program's standards (Metro Richelieu Inc. 2015). The lack of a smiley-face on a tag provides space for consumer confusion, as it is unclear whether the product is new or received an understated poor rating. For example, deli meats are seen as a "good choice" for a 55 g serving, with no added nitrates, shortening, or hydrogenated oil, and is 5 g of fat or less and 360 mg of sodium or less (Metro Richelieu Inc. 2015).

Interestingly, Sobeys Inc. has taken a decidedly different route to the marketing of healthful foods. Rather than offering an in-store rating system, Sobeys has paired with celebrity chef Jamie Oliver in support of their social media-based #BetterFoodforAll campaign. The campaign name aligns itself with Sobeys Inc.'s slogan of Better Food for All, (Better Food For All 2015) and encourages shoppers to eat healthier by offering recipe suggestions, in-store testing and education, and to share their #BetterFoodforAll stories via Twitter, Facebook, and the Better Food Blog (Better Food For All 2015).

Conclusion

Food retailing refers to the process of selling and procuring food goods, most often from a retail outlet, such as a big box brick-and-mortar store. Discussion on of the problematics of corporated food retailing was presented to make an argument for the increasing financialization of food and the emergence of retailing outlets as merchants of nutritional advice. Discussion surrounding the prominent role of food retailers in food procurement, including outlining the dominant Canadian food retailers, was provided above.

Introduction

As a wave of severe global crises swept across the world at the turn of the twenty-first century, a series of food riots broke out in many developing countries, including Indonesia, India, Mexico, and Brazil. These food riots, often centered on one iconic staple food item such as rice, tortillas, or onions, usually consisted of looting and pillaging stores, fast food restaurants, and supply

depots, blockading farm and supply trucks, or protests in town squares. These items symbolized people's intense frustration and anger at being trapped in a global economic web in which they seem to have no agency. Government officials have been rightfully terrified of the potential for anarchy that exists if people do not get enough to eat, particularly enough of certain foods deemed essential and irreplaceable. Can anything ever stem this tide of need?

Cultural historian Robert Darnton once posed the question, "[Can] riots be understood as something more than mindless violence? [Are] they saying something? [Can] they be read?" (Darnton 1992, p. 44). Building off of Darnton's questions, one asks: Is it possible to make sense of food riots, particularly those in the past, by "reading" them? Can one gain increased understanding by paying attention to the one item – the bread, meat, or rice – that is held up as a symbol? What are the ethical implications of food disturbances when set against the backdrop of Western abundance, and how do these disturbances differ from those in developing nations?

A survey of histories of food riots reveals that scholars have understood public food disturbances in a number of illuminating ways, including as a preindustrial expression of collective action, as a gendered form of collective protest, and as a form of nationalistic display and identity tied to the consumption of material goods. Only a very few have employed a sustained, cultural exploration of the very foods at the core of the disturbance (the bread, meat, rice, or milk) – the deprivation of which stirs people to the point of collective action. Such an examination can provide rich information about the connection between food, cultural/national identity, and the ethics of policies that lead to scarcity and abundance.

To begin exploring these questions, it is important first to examine the relationship among collective identity, food, and collective protest. Food, at the base of civilization, contains deep, multi-layered meanings and is a strong component and shaper of collective as well as an individual sense of identity (Narayan 1995). Whether unprocessed or minimally processed foods (wheat, cooking

oil), industrially manufactured items (Coca-Cola or commercially produced baby food), or hand-made creations (tamales, holiday cookies), people imbue particular foods with deep-seated meaning and emotion, regardless of whether they are involved in its production (farmers, processors) or merely its consumption (tea drinking in Europe or North America). How and why these foods accrue special meaning can vary widely: method of preparation, tradition, particular "flavor principles," perception of purity, religious or political significance, signification of wealth or status, or any combination of factors. Whether through government intervention or the vicissitudes of a "free market" economy, a restriction of the availability of these meaning-rich foods carries significant social weight and can function as a catalyst for collective protest. This continues to prove true not only in relatively isolated communities, but in the ever-changing global villages of the twenty-first century (c.f. Bell and Valentine 1997, p. 191).

For the purposes of this inquiry, "food riot" can be defined as any gathering, whether planned or spontaneous, that may begin peacefully (such as a "food protest") but evolves into disorder, leading to loss of control, violence, bodily harm, or damage to property. The terms "food riot" and "food protest" can be understood and discussed together under the phrase "food disturbance" (Gilje 1996, p. 4). Food disturbances appear when people lack complete control of their own food supply: either they do not grow all or some of it, they are taxed by landlords or governments, prices (set by others) are beyond their notion of a "just price," or they are unable to freely determine the disposal of any surplus. Developing countries are more prone to food disturbances than industrialized ones: countries with developed transportation and communication systems, and the ability to stockpile food for times of need or subsidize its price, are more able to quickly redistribute food as needed. Food riots were especially frequent in the sixteenth through eighteenth centuries, then declined dramatically in number until the 1970s, when riots began again in earnest in developing countries as a result of severe economic austerity measures, including the removal of subsidies on food (Walton and Seddon 1994, p. 24).

Examining riots can reveal much about the political, economic, social phenomena of an era and allows better understanding of people who are neither wealthy nor politically prominent – the people whose lives do not normally become a part of the public historical record. Scholars have argued that despite the apparent unpredictability of time and place of riot and level of organization of rioters, an underlying order appears to exist: food rioters often act in logical, deliberate ways. That is, crowds do not just pillage any store, for example, but those stores that they feel have unfairly inflated prices. Historical and cultural context appears to play a key role in rioting.

Historians have generalized riots into three main categories: first, a blockage or *entrave* where protesters blocked shipments of grain or other foodstuffs; second, the price riot or *taxation populaire*, where peasants seized the goods from a retail shop whose prices were deemed too high, which would then be sold for a “just price,” and often (amazingly) the money paid to the merchant; and finally, the market riot, where stores and supply depots are looted to protest high prices or the lack of goods (Tilly 1996, pp. 231–234; Thompson 1971, pp. 76–77; Gilje 1996, p. 6; Walton and Seddon 1994, pp. 25–26). Modern-day riots tend to conform to the latter category of market riots, characterized by looting and destruction of property. Additional twists include calculated demonstrations where the food at issue is ceremoniously dumped on the grounds of, for example, the local government headquarters. Twentieth-century food boycotts have proven particularly effective when centered on one item such as milk, bread, or grapes or on a single manufacturer, such as Nestlé (Linden 1994). Boycotts can evolve into full-fledged food riots if participants harass or attack those purchasing a targeted item or frequenting a targeted store.

A Historiography of Food Riots

Why do people riot over food? The obvious answer, that they riot because they are hungry, *fails*. Most who are poor and hungry do not riot. Moreover, why do people riot over particular

foods and not others? Tortillas not chiles? Meat not cheese? What intervening variables determine who riots? As mentioned, historians have analyzed and explained food riots in the following ways: as collective action representing the “moral economy” of an era, as part of a so-called female consciousness, and as an exhibition of nationalism/patriotism.

The “father” of food riot history, the British Marxist historian E. P. Thompson, in 1971 published the article, “The Moral Economy of the English Crowd in the Eighteenth Century.” With “The Moral Economy,” a witty, erudite, and detailed analysis of food riots in England, Thompson provides a “thick description” of food rioters’ motives in preindustrial England, an era when subsistence riots happened with great frequency. Thompson, using class as his organizing principle, argued that English peasant bread riots were symptomatic of a society caught between changing economic and political forces, of an England in the midst of moving from a looser collection of landed gentry to a stronger state, and from a mercantilist, feudal economic system to one of laissez-faire market capitalism. As England moved from a feudal system that provided bread at “just prices” (a reduced price for the poor as part of the communal moral ethos) to a market economy, which abandoned the notion of the just price, peasants rebelled and rioted. To the rioting peasants, the new system abandoned the long-held social pact that entitled them to affordable bread. People, argued Thompson, rioted not only because of hunger, but also out of a sense of injustice. Conflicts, Charles Tilly concurs, “occurred not so much where men were hungry as where they believed that others were unjustly depriving them of food to which they had a moral and political right” (Tilly 1975, p. 389). Eric Hobsbawm, similarly arguing that food disturbances were a preindustrial mode of exhibiting anger over economic and social inequity, called these “collective bargaining by riot” (Hobsbawm 1959, p. 110). As the peasantry became the industrialized working class, conflicts over food were absorbed into and displaced by organized labor strikes. This explains why the number of food riots diminished considerably in the nineteenth

century and beyond. Although scholars have taken issue with Thompson's moral economy theory – some insist that the theory should focus on the newly emerging middle-class dissatisfaction, while others point to prevailing anti-Semitism and local begging customs as factors or see the community or national context as more important – nearly all historians studying food riots pay homage to E. P. Thompson for his path-breaking work in creating a multi-dimensional understanding of food rioting and rioters (Arnold 1979; Bohstedt 1988, 1992; Booth 1977; Gailus 1994; Kaplan 1985; Rogers 1987; Shashan 1980; Tilly 1983; Taylor 1996; Williams 1984).

Since women as well as men participated in food riots, in recent decades many historians have employed gender as a category of analysis (Davis 1996; Engel 1997; Frank 1985; Hufton 1971; Hyman 1980; Kaplan 1982; Ryan 1989; Smart 1986; Taylor 1996). While not disagreeing with the moral economists, historians such as Temma Kaplan, Phyllis Hyman, and Dana Frank point out that despite the decreasing number of food riots in the nineteenth century, food disturbances nevertheless continue. Moreover, they argue, food rioting takes on a noticeable female persona, in part because labor unions largely excluded women. Temma Kaplan, studying early twentieth-century food riots in Barcelona, argues that women participated in food riots as an extension of their roles as caregivers for home and family. Women who accepted the traditional division of labor, argues Kaplan, could be radicalized to action in the public sphere when prevented from fulfilling their domestic duties, particularly the feeding and care of their families. Female participation in food disturbances "politicize[d]... the networks of everyday life," as women extended their domain and sense of obligation into the public sphere (Kaplan 1982, p. 545).

Dana Frank and Paula Hyman, studying early twentieth-century food riots in New York City's Lower East Side, concur with Kaplan. Hyman examines a 1902 kosher meat boycott organized and dominated by women that at one time brought crowds of up to 20,000 protesting the high prices of meat. The boycott frequently erupted into

violence, including women breaking into butcher shops and flinging meat into the streets and assaulting not honoring the boycott. While the women "did retain a traditional sense of a moral economy in which food should be available at prices which the working classes could afford," explains Hyman, in a nod to E. P. Thompson, "they were not simply expressing traditional forms of cultural resistance to industrial society imported from the Old Country," but providing evidence of a "modern and sophisticated political mentality emerging in a rapidly changing community" (Hyman 1980, pp. 97, 92). Dana Frank, examining the 1917 cost-of-living protests, similarly sees an emerging female consciousness. As New York's immigrant Jewish women protested against rising food prices, explains Frank, they "demonstrated their own perceptions of political economy: who they believed was in power; what they thought should be done to alleviate their distress, and, most importantly, how they believed they as women could affect the economic system in which they were enmeshed" (Frank 1985, p. 256. See also, Frieburger 1984).

While some have returned to topics such as the French Revolution to employ gender as a category of analysis (Bouton 1990), not all historians regard gender as a useful framework when examining food disturbances (Bohstedt 1988). For example, Iain J. M. Robertson argues that when investigating women's participation in food riots, at least those in turn-of-the-(nineteenth)century Scotland, using gender as a category of analysis obfuscates the fact that men and women held notions of ownership over the land equally. Thus, when denied ownership of farmland deemed to be theirs, they rioted in the same way for the same reasons. Assuming that women's protest is distinctly different from "'normative' masculine protest, and derived from their household role rather than from an underlying legitimizing ideology shared with their male counterparts," argues Robertson, does a disservice to the women who participated as equals with men (Robertson 1997, p. 187). Robertson neglects to discuss, however, those food disturbances that were comprised largely or exclusively of women.

Along with the moral economy thesis and gender as an analytical framework, *one can* gain insight into the meaning and nature of food riots *through* the examination of cultural meanings of consumption and their connection to nationalism. Two American colonial historians, Barbara Clark Smith and Timothy Breen, have examined food disturbances before and during the American Revolution as evidence of a growing sense of nationalism. In her study of over 30 food riots during the American Revolution, Smith sees such disturbances “at the intersection of several streams of historical experience” and acknowledges as pertinent both the moral economy and the female consciousness theses (Smith 1994, p. 3). Not only do they contain “elements of ‘the common people’s politics’ in England and America,” in their focus on the just price, but since women conducted nearly one-third of riots, Smith argues, they also must be examined in light of how women participated in community life (Smith 1994, p. 5). Looking at food riots as directly stemming from the Revolution, as “a patriotic action” not dissimilar from facing the British army (Smith 1994, p. 6), allows understanding of how food rioters, through their actions, “situated themselves as participants in the patriot cause” (Smith 1994, p. 8).

While Smith uncovers elements of nationalism in the act of rioting, T. H. Breen recognizes a growing sense of nationalism developing through the item (including food items) being rioted over. In his 1988 article, “‘Baubles of Britain’: The American and Consumer Revolutions of the Eighteenth Century,” Breen explores the relation between the growth of national consciousness and the American rejection of the “Baubles of Britain.” While noting the importance of women in colonial food disturbances, Breen focuses his attention on the fact that manufactured goods imported from Britain, for the first time readily available to so many people, resulted in “the standardization of taste” (Breen 1988, p. 82). In the decades leading up to the Revolution, consumer goods took on “a radical, new symbolic function” of political proportions. This politicization provided a “shared language of consumption,” providing a common experience and knowledge base

for colonists of all classes, uniting them enough to wage war against the mother country (Breen 1988, p. 76). While Breen does not limit his analysis to food but explores the meaning of consumer goods of all kinds, Breen does focus on the struggle over tea – for Americans one of the best-known and loved stories of the Revolution. “Throughout America,” Breen relates of the infamous Boston Tea Party, “the ceremonial destruction of tea strengthened the bonds of political solidarity” (Breen 1988, p. 99).

While this admirable work on food riots and protests contributes much toward explaining people’s *mentalities* and motives for rioting, missing is an in-depth examination, a Geertzian “thick description,” of the foods themselves. A sustained, cultural exploration of the very food at the core of the disturbance – the tea, meat, milk, or even such modern industrialized products as Coca-Cola – can provide rich information about the connection between food and cultural/national identity. A foray into the meanings of the foods themselves in their historical and cultural context can add yet one more important layer of understanding.

In addition to Breen, several of the works previously discussed do hint at such analysis. For example, although Dana Frank focuses on gender, she does touch on the symbolic significance of the foods being rioted over. While the price of food seems to have been high in general, according to Frank, the Jewish women were particularly focused on boycotting chicken, onions, potatoes, and fish. Frank writes:

[M]any women initially joined out of a sense of limits reached, as in the case of the woman who asserted her continuing right to butter. Those limits boiled down to an unwillingness to altogether abandon traditional foods. Potatoes, onions, and chickens were dietary staples to which they believed they had a basic right if they were to fulfill their responsibility to truly sustain their families. More importantly, the rituals of preparing kosher foods played a crucial role in the religious and cultural self-definition of New York’s immigrant Jewish people. . . . Women bought and served traditional foods not only out of mere habit, but also because those foods

expressed their commitment to a religious life (Frank 1985, pp. 276–277).

As Frank notes, these foods were important, even crucial, parts of the Shabbat dinner. Without them, could there even be a Sabbath seems to be the unspoken question. Fish, Frank somewhat inadequately explains, was boycotted because it could not be served without the boycotted onions. Moreover, the foods city officials tried to introduce as substitutes reveal all the more how culturally important chicken, onions, potatoes, and fish were. The large quantities of rice, smelt, Brazilian beans, and hominy that the city provided as substitutes were (not surprisingly) unequivocally rejected. A thick description of these foods in their historical and cultural context could provide further compelling analysis. Paula Hyman, in her gender-focused analysis of the New York City kosher meat boycott of 1902, similarly points to cultural elements: “The neighborhood, a form of female network, thus provided the locus of community for the boycott. [A]ll were giving up meat together, celebrating dairy shabbosim together, and contributing to the boycott fund” (Hyman 1980, p. 99). Hasia Diner examines the cultural and social meanings of the turmoil and contestation that existed among Jewish immigrants, including such food disturbances as boycotts and riots (Diner 2001). Finally, as anthropologist Sidney Mintz illustrates in his exceptional work on the historical, cultural, political, and economic meanings of sugar, there is much more that could be done on the cultural meanings and functions of tea – itself purely a product of British colonialism – in colonial America that can provide even more evidence of its centrality to life at the time and thus the catalyst for boycotts, riots, and even revolution (Mintz 1985).

While this survey of the literature of food disturbances is not exhaustive, Benjamin Orlove’s article “Meat and Strength: The Moral Economy of A Chilean Food Riot” is the only sustained cultural analysis of a riot in terms of the food being rioted over identified to date. Orlove’s work builds on Thompson’s moral economy theory to argue that in 1905 the middle classes of Santiago, Chile, rioted over rising food prices because it prevented them from purchasing their

accustomed quantity of meat. In this historical and cultural context, in this particular “moral economy,” (Orlove 1997, p. 255), the ability to consume meat reflected one’s place in the rigid social and political hierarchy of Chile. No longer being able to afford meat “undercut a deeply held sense of [Santiagoans’] social position” (Orlove 1997, p. 256). Orlove argues that “It is the distinctiveness of the specific moral economy [of Chile in the early 1900s] that allows a piece of beef to make the difference between an acceptable and unacceptable pot of stew” (Orlove 1997, p. 260).

Cultural Meanings of Food in Food Disturbances: An American Backdrop

It is possible to point to food riots in recent US history on which to focus a sustained cultural analysis of the foods involved. In comparison to most other countries in the world, the United States ranks high if not the highest in the number of calories per person available for consumption in the food supply. Food problems in the United States are less about hunger and more about health deficiencies resulting from too much food or too much of the wrong kinds of food.

Any analysis, then, of food disturbances in the United States must be made within the backdrop of the entrenched notion of abundance. Economic historian David Potter’s 1954 study of American culture and politics in light of the abundance of material wealth, *People of Plenty*, argues that the United States and its citizens have been shaped, blessed, but also at times intellectually and socially hindered by living in one of the most resource-rich and economically successful countries in the world. This long history of plenty – a product of both natural resources and technological innovation – has shaped notions of such abstract terms as “freedom,” “democracy,” as well as immigration, foreign policy, and assumptions about individualism. As ideas such as “abundance” and “democracy” are conflated, many Americans (and, indeed, many immigrants to the United States) (mistakenly) equate such political notions as liberty and equality with capitalism. Other countries’ experiences do not suggest the

same equation. Even though all Americans have not partaken of this abundance, Potter insists that this promise of prosperity has shaped both the culture at large and individuals in particular. Potter attributes low political activism and voter participation, the lack of a viable socialist movement, and the American myth of classlessness to this abundance, despite the ever-growing economic disparity between rich and poor (Bentley 1995; Potter 1954).

Food is a central element of the American brand of abundance. Food disturbances can differ in shape and context between industrialized and developing countries. In the 1930s and 1940s, for example, farmers in the United States protested the removal of price supports, women boycotted dairies over high milk prices, and the public decried the destruction of edible grain and pork during the Depression. Other food disturbances have occurred since then, but most often in the form of boycotts and hunger strikes to protest and publicize a particular social or political cause (Gilje 1996, pp. 149–169; Poppendieck 1986; Bentley 1998, pp. 56–58). While significant, these are not the food riots of hungry, angry people hoping they have enough food to feed their families. For example, late-1990s riots on college campuses over restrictions on alcoholic beverages (“Student Rioters Demand the ‘Right to Party’” 1998) need to be analyzed as “food disturbances” not only within this context of abundance, but against the unique backdrop of the history and culture of alcohol in the United States: the temperance movement, prohibition, American Protestantism, fears of non-Protestant immigration, and social and symbolic meanings of alcoholic beverages (e.g., Edmunds 1999; Fuller 1996).

While Potter’s ideas are significant and compelling, they are subject to debate. For example, Mark Weiner, in his exploration of Coca-Cola’s rise to becoming a totem drink During World War II, effectively details the cultural, social, political, and economic significance of Coke in the United States during the war and addresses the connection between consumerism and democracy (“Consumer Culture and Participatory Democracy: The Story of Coca-Cola During World War II,”). Weiner queries: What does the promotion of a highly

sugared, caffeine-laced soft drink mean? Exploring what corporate image makers wanted Coke to represent to Americans and what Coke actually meant to civilians, distributors, and soldiers, Weiner describes the influence of commercial capitalism on democracy not as largely negative, as Potter and others generally conclude, but as complex and layered in its meanings. As advertisers, American corporations, and the US government cooperated to rally the American home front behind the war effort, Weiner *shows* how corporate conglomerates defined war aims in terms of commodities. Yet, Wiener argues, the soft drink gained this prominence in part because Coca-Cola held important personal meanings for many Americans, to the extent that it stirred political action and symbolized powerful ideas about American democracy.

In demonstrating the iconic nature of Coca-Cola, Weiner convincingly argues for the cultural importance of the soft drink in the lunch counter sit-ins of the post-World War II Civil Rights era. Following Breen’s lead, Weiner sees the possibility for “participatory democracy” existing in consumer goods. In this case, democracy became the right to sit at a drugstore lunch counter and order a cold glass of Coke, something not available to African-Americans under the Jim Crow laws of the South. Being denied access to the lunch counter at Woolworths symbolized in part the denial of full citizenship to African-Americans (Weiner 1996).

There is plenty of work to be done exploring the cultural meanings of foods in food disturbances not only in the United States but globally as well. Historians of Europe, for example, have employed the backdrop of World War I and II to detail fine accounts of bread riots in Russia and of women’s protests over food scarcity in WWI Berlin and in 1942 Vichy France (Engel 1997; Davis 1996; Ryan 1989). Yet there is room for so much more. One cannot think of food disturbances in European countries without mentioning the late-1990s protests by the French over American tariffs on foie gras. Images of a ransacking of a McDonald’s and of French chefs and restaurant owners throwing food at the French Parliament to demand lower taxes are prime moments for cultural analysis (“Chefs Protest Tax”; “Farmers

Protest” 1999). Also, ripe for exploration are the cultural and symbolic meanings of the rice, tortillas, onions, and bread of the 1990s food riots, as well as such food disturbances in history as the salt demonstrations in 1940s colonial India. Such examinations will reveal much about the ethical implications of food riots from a historical perspective.

Summary

A survey of histories of food riots reveals that scholars have understood public food disturbances in a number of illuminating ways, including as a preindustrial expression of collective action, as a gendered form of collective protest, and as a form of nationalistic display and identity tied to the consumption of material goods. Only a very few have employed a sustained, cultural exploration of the very foods at the core of the disturbance (the bread, meat, rice, or milk) – the deprivation of which stirs people to the point of collective action. Such an examination can provide rich information about the connection between food, cultural/national identity, and the ethics of policies that lead to scarcity and abundance.

Introduction

The alimentation sector, as other types of industries, has to constantly respond to the changing conditions of modern times. The most important determinants responsible for alternations are connected with the reality of a contemporary epoch. First of all, the twenty-first century is influenced and shaped by the growing role of new technologies. Thus, the Internet, offering fast communication to a relatively large number of addressees, becomes an important medium in contacting current and potential stakeholders in the food industry. Secondly, the mobility of modern times concerns not only consumers but also food products since nowadays customers may have access to comestibles coming from very distant countries. In this case, such aspects as proper transportation, storage, and methods of dish preparations should be treated with great consideration. Thirdly, modern agriculture differs from the one that could have been observed in the previous centuries; the development of, among others, modern medicine, technology, and biology

has changed the ways plants and animals are farmed. In addition, technological advancements have altered the ways of preparing, serving, and storing food. Furthermore, modern lifestyle has led to a new understanding of consumption and nutrition and the role of food in one's life. Taking all the mentioned issues into account, it is communication that plays a very important role in the alimentation sector, offering information how food is (and how should be) manufactured, transported, stored, and consumed. Analyzing all aspects of food issues, various hazards are connected with every stage of food production, distribution, and consumption, and, consequently, food risk communication is crucial in communicating alimentation challenges and threats to diversified groups of stakeholders, including, among others, food producers, public authorities, media, local communities, and various consumers.

Defining the Term *Food Risk Communication*

Discussing the place of communication in the discourse on alimentation threats, food risk communication, risk assessment, and risk management constitute the essence of food safety risk analysis. As far as the elements of food safety inquiry are concerned, risk assessment can be described as the process of evaluating risks by applying both qualitative and quantitative approaches, coming from various disciplines, such as social studies, humanities, management, economics, biological and chemical domains, etc. Regarding risk management, it concerns the estimation of available options connected with risk avoidance and the assignment of control strategies to ensure protection. Since risk communication is needed to define and implement best management decisions (FAO/WHO 2001), interactions focusing on food risks are connected with creating and incorporating methods related to food management. Thus, food risk communication can be defined as a set of tools responsible for creating, implementing, executing, and controlling aims, strategies, and procedures to deal with

food-related threats. Looking at this issue from the perspective of processes and stages, food risk communication is a term that encompasses various notions related to the chain of comestibles, especially the potential and real dangers of food production, preparation, distribution, storage, consumption, and utilization. Thus, food risk communication encompasses various forms of comestibles, from, e.g., the state of being a grain, through the periods of fruit and dish, to the stage of organic waste. All the mentioned "embodiments" of food are potentially subject to the discussion of challenges and threats in the sector of comestibles.

Elements of Food Risk Communication

As far as elements of risk communication are concerned, they can be divided into *care communication*, *consensus communication*, and *crisis communication*. In the case of care communication, discourses have to take into account the lifestyle of diversified audience to adjust risk messages. Analyzing consensus communication, communicators have to observe the opinions, anxieties, and beliefs of stakeholders. Regarding crisis communication, the culture of a target audience should be taken into account in preparing and disseminating messages on crisis (Lundgren and McMakin 2009). Applying the mentioned typology, the following classification for food risk communication can be created. *Food care communication* encompasses diversified risks related to food consumption. Thus, such notions as food selection, ways of preparing food, and places of consumption determine food care communication. Thus, consumers should be informed how improper ways of preparing dishes may lead to health hazards. The next element, *food consensus communication*, involves opinions, knowledge, and fears regarding food. Consequently, the ways risks are perceived by various stakeholders should be visible in the applied communication tools and strategies. Moreover, the discussion on threats should be tailored to stakeholders' interests, knowledge, and capabilities. For example, information on food-borne diseases

is constructed in a different way when directed at specialists and when the general public is addressed. On the other hand, in *food crisis communication*, speakers have to observe such issues as the culture of a target audience in communicating information on food risks. It involves, e.g., taking into account the type of farming in a given country, climate conditions that influence food production and storage, eating habits, and dietary preferences. Thus, the cross-cultural aspect of food risk communication involves taking into account individual and group differences as far as, e.g., the attitude to risk and the way it is communicated are concerned.

Participants in Food Risk Communication

The participants of discourse on food risks can be divided into different ways. One typology involves the role they play in the comestible chain. Private food producers include both individual farmers or producers who perform their duties mainly themselves as well as companies and manufacturers who operate on the food market on a large scale. Another group encompasses public authorities who have some executive power over food producers. Their activities in the food sector may involve, among others, introducing new legal regulations concerning comestibles or exercising control over food production. The next important group constitutes of distributors who serve the function of intermediaries between producers and customers. Moreover, media belong to active participants in the food chain since both standard and novel methods of mass communication aim at informing individuals about challenges related to the food sector. A local community encompasses the group of stakeholders that is not necessarily involved actively in the food chain, but it is interested how the performance of food producers influences their community (potential pollution of the local environment, more jobs for local people, etc.). It should be stated, however, that many food stakeholders constitute consumers themselves. This type of participants includes the group of active

users of a food product as well as the category of potential customers who may opt for it in the future. Customers can be further subcategorized by taking such aspects into consideration as age, gender, marital and economic status, etc. Another method of classifying contributors to food risk communication is connected with how active various stakeholders in the discourse on food threats are and which stage of information dissemination they participate in. For example, food health authorities play an active role in creating information on risks, whereas media, including new social media, are responsible for information spread. It should also be stated that the role of participants should not be limited by any factors. For example, knowledge of a language should not restrict the access to important information. Thus, in the case when individuals represent different linguistic communities, attention should be focused on how messages should be communicated to address various language groups. The same concerns people with disabilities. Messages should be prepared and disseminated in the ways that make disadvantaged groups access the data on food risks. In addition, an important notion in food risk communication is related to the position of interlocutors. Thus, in the case of food risk discourse, it should enhance the dialogue between food authorities and food stakeholders. Since active communication with stakeholders is especially important in risk and crisis communication (Bielenia-Grajewska 2011; Lundgren and McMakin 2009), mutual engagement in discourse is crucial in food-related risk situations, such as food poisoning and food-borne diseases.

Topics in Food Risk Communication

Popular topics in food risk communication involve the following issues: probability that past food-related problems may reappear, dangers related with different stages in food cycles, effects of food-related risks, and trust in food-related aspects of modern life. As far as the scope of interest is concerned, communication regarding food risks concerns various issues, such as

food irradiation (Thompson and Knight 2006), genetically modified food (Qin and Brown 2006), food recall (Nucci et al. 2009), food contamination (Jacob et al. 2011), food-borne diseases (Bielenia-Grajewska 2014), food allergies (Rachul and Caulfield 2011), and food safety regulations (Winickoff and Bushey 2010). The interest in topics depends on the target audience; there are issues that are potentially directed at the general audience, whereas other notions focus on the needs and expectations of a selected community. Some of them attract a relatively large number of stakeholders (e.g., food-borne diseases, food additives), whereas some of them receive the attention of an interested community (e.g., food poisoning in a local bar or a canteen). For example, taking into account, e.g., the contamination of food for babies, the groups primarily interested in this issue are parents, babysitters, owners of nurseries or kindergartens, and others connected in some way with feeding young children. It should be stated, however, that a topic that was supposed to be of local interest often becomes an issue of global interest. It may be the case of food-borne diseases that start in a small locus (a bar, a canteen, a shop) and then turn out to affect a relatively large number of individuals, located in various settings and coming from different backgrounds. Taking into account the mentioned topics discussed in the literature of risks related to agriculture and food business, several of them have received broad coverage in the press. Discussions on them are often accompanied by information campaigns on risks and threats related to food consumption conducted by either producers or public authorities. Topics that engage a relatively large number of potential interested parties are food-borne diseases, such as *Escherichia coli*, BSE (bovine spongiform encephalopathy), salmonella, or listeria, that receive broad coverage in the international press when new cases are reported. Another popular discussion point is the role of modern technological advancements in food production. These topics include GMO (genetically modified food), the role of pesticides in farming, and the usage of additives in food.

Selected Cases of Food Risk Communication

The cases related to food risk communication can be classified, among others, by taking into account their nature. One of them is the coverage of diseases that have rapid and violent outbreak. Food-borne diseases belong to this group. An example of food risk communication case can be the outbreak of *E. coli* epidemics in Germany in May and June 2011. The epidemics started in Hamburg, and later 16 countries reported the cases of this rare serotype of *E. coli*. Many people were affected by the disease; at least 50 individuals died, more than 4000 were sick, and 852 suffered from kidney-damaging hemolytic uremic syndrome (HUS). As far as finding the cause for outbreak is concerned, since patients reported eating vegetables, crude vegetables were the first suspects of the epidemics. Laboratory tests proved that pathogenic *E. coli* was on Spanish cucumbers and, consequently, these vegetables were first associated with this outbreak. However, further tests showed that the bacteria found in these cucumbers were not responsible for the epidemic outbreak. Thus, researchers and public authorities had to continue their investigation in searching for the comestibles that caused epidemics. The European health officials checked more than 10,000 samples of food, but the outbreak strain was not detected. Another method led to the uncover of the source of infection; checking bills from company cafeterias where the patients were eating helped to discover that the served sprouts were the cause of illness. Thus, the investigation was further focused on how sprouts were infected. As far as food risk communication is concerned, some items turn out to be especially important in the coverage of this *E. coli* outbreak. First of all, sprouts were overlooked by patients in their description of what they have eaten. Thus, other food products were originally investigated by researchers and officials. Secondly, such information sources as menus, shopping lists, and bills are very important in investigating the sources of outbreak since they can be studied independently of what patients report (Flynn 2011). Thirdly, some vegetables were misidentified as the source

of outbreak, and after further tests, the responsible factor of epidemics was found out. Thus, different channels of food risk communication were constantly updated to inform stakeholders about the newest findings related to the situation in focus and how investigation was conducted. It should also be added that due to the high mobility of people and products, information on *E. coli* outbreak received vast coverage in international media. Thus, this case shows that food risk communication should encompass different research materials as well as diversified information channels to keep the broad public informed on threats in the alimentation sector. Another group of cases is related to issues that are not as dynamic in character as the above-discussed example of food-borne disease but are characteristic of long-term influence on human beings. The examples include using additives in comestibles. These issues receive regular coverage in the press and in scientific publications, often following discussions on new regulations of colorants or preservatives, of natural and artificial origin, used in food production. Such data leads to customers being more informed about the food they consume and offer.

Food Risk Communication and Types of Risks

Food risk communication can be viewed from the perspective of threats related to domains associated with different stages of the alimentation chains. Thus, one typology can encompass the risks associated with farming, food production, and food consumption. For example, *farming risks* can include various threats connected with the extensive use of pesticides, damages done by insects, or natural disasters. The second group, *food production risks*, encompasses the hazards connected with polluting or spoiling food in the processes of manufacturing comestibles. This element of typology includes producing food outside the factories (e.g., at home). The third category, *food consumption risks*, are associated with improper storing or serving food. The mentioned risks can be investigated further, by taking their

nature into account. For example, *institutional risks* may enclose the decision of authorities (or its refusal) about subsidies or other forms of institutional help. *Market risks* include the factors responsible for successes or failures of products. For example, due to changing dietary preferences of the general public, there can be a lack of interest in some offered comestibles. In addition, *natural risks* environ threats connected with natural disasters or performance of animals. An example of such a risk can be the increase of population of some insects or animals that consume corn or the flood that damages the fields. *Financial risks* involve problems with access to credits, high interest rates, and irregular payment flows. An example of this type of risks is the delay in payments for sold food products. *Technological risks* involve the difficulties in having access to technological advancements. Apart from the external risks, food risk communication is also connected with threats on the personal level. *Individual risks* are directly connected with the performance of the person responsible for a given stage in food production. To such risks may belong the following examples: wrong decisions made by the farmer or a longer illness of a farmer (especially in the case of small farms run by one person). Food risk communication can also be discussed by taking into account types of risks. Since food risks can be classified into imaginary and real ones, the way they are communicated is also different. As far as the ones with no scientific record are concerned, they comprise individuals' attitudes to some food products and their opinions about their negative effects. One of the unproven fears toward novel comestibles is called *neophobia*; individuals who are neophobic about new food think it may be toxic. It may concern toddlers and young children as well as adults. As far as the group of adolescents is concerned, neophobia is greater among old people and those of low educational level (Frewer 2012). In this case, the role of information is crucial in showing people facts connected with food that may help them opt for new comestibles. Another important notion is individuals' past experience with food. Satisfaction or dissatisfaction with previously eaten products determines their future selections. Apart from the mentioned

social determinants, attitudes to risks are shaped by individual perceptions. Some people may think they are less prone to risks than other individuals, and some are more pessimistic about health concerns than average representatives of a given group. It is especially visible in the case of food-borne diseases and the attitude of affected parties to food risks. After becoming acquainted with news on food-borne diseases, individuals may feel that risks do not concern them since a different geographical region is mentioned or a different age group is described as the one who has suffered during pandemic outbreaks. The attitude to food risks also depends on individuals' health and dietary requirements. For example, people suffering from food allergies may find some substances dangerous for their health in a product being safe for other individuals. Another feature characteristic of risk perception is the tendency to shed responsibility on other people. According to some studies on the meat industry, customers think that farmers are more accountable for safety than they are in reality, whereas farmers think customers are more responsible than consumers believe they are. Consequently, farmers and consumers perceive their role in the food system as less responsible than it really is. In addition, consumers think that the highest responsibility is located at the middle level in the meat food chain, whereas farmers think that the later stages in food production are the most responsible ones (Erdem et al. 2012).

Sources of Information on Food Risks

Taking into account the type of information diversified stakeholders are looking for, various information sources can be enumerated. The channels that are used for communicating risks related to food consumption are different. Their selection depends on target stakeholders as well as the type of food risks that are going to be communicated. Discursive methods can be classified as traditional and modern ways of communicating food risks. The traditional ways of gathering information encompass, among others, books, scientific journals, and brochures, whereas the

modern ones include social media and various online methods of communication. Regardless of the variety of information on food risks, food packages belong to the most often used sources to obtain data on food characteristics. Consumers read labels to search for details on expiry dates, list of ingredients, and characteristics of nutritional elements. Apart from labels, individuals may use scientific and press articles to access information on comestibles they are looking for. Risks are likely to become a topic of interest in media since they often rely on the both verbal and nonverbal elements that strengthen messages. As far as the strong visual impact is concerned, a text may include, e.g., pictures of suffering (Bennett 2001). Moreover, food risks concern everyone, directly or indirectly, depending on which type of food danger is taken into account. In addition, food risks are very difficult to judge, and the number of those who are likely to suffer is hard to estimate. Thus, the mentioned features also make it a more dramatic topic. With the growing popularity of new technologies and the Internet in the reality of the twenty-first century, such tools of communication as e-mails, discussion forums, and other forms of social networking become the place of information exchange on food risks. The Internet offers individuals the possibility to obtain data when they do not have traditional media (e.g., newspapers, radio programs) at their disposal, for example, during a trip. Moreover, such a piece of information can be distributed quickly and at relatively low cost (Bielenia-Grajewska 2011). Thus, online applications facilitate food risk communication with a relatively large group of interested parties, without investing a great deal of time and money. It should be highlighted that in order to reach the highest possible number of stakeholders diversified methods and tools of communication should be employed. Thus, both standard and new forms of communication exchanges take part in effective food risk discourse. The selection of information medium depends, to a great extent, on individual characteristics. Food risks can be communicated in formal and informal ways. Informal communication (e.g., conversations in the workplace) about food safety can often have more impact on workers'

behavior than formal forms of communications (e.g., e-mails sent to all employees).

Tools of Food Risk Communication

Effective food risk communication demands diversified and well-selected tools that allow for proper discourse. In order for the message to be created, communicated, and comprehended, communicators have to select such communication tools that will foster the understanding of food issues among diversified interested parties. Different linguistic, paralinguistic, and nonlinguistic elements of communication facilitate the understanding of food risks. As far as the linguistic dimension is concerned, figures of speech, such as different words or phrases describing the surrounding reality, shape the way risks are perceived and understood. Although both literal and non-literal linguistic elements mirror and create the environment, figurative language that offers a novel understanding of regular words and phrases is often used in the discussion on new, difficult, or complicated matters. Thus, such tools as metaphors, similes, and idioms are often employed in food risk communication. Among symbolic methods of communication, metaphors constitute one of the most often used communication tools in the discourse on food risks. The reasons for the popularity of metaphors are different. One of them is related to the role of metaphors in journalism. Figurative language induces interest in texts, and metaphors are important tools in the informational competition among journalists since the aim of a media person is to draw the attention of readers to his or her article. Thus, metaphor can be a tool for gaining information advantage and, consequently, a greater number of readership. Additionally, metaphors can also be used as an instrument of creating one's own journalistic identity, an outstanding writing style that can be easily recognized by readers. As far as the organizational dimension is concerned, metaphors shape the way organizations are perceived since metaphors provide a bridge that facilitates innovative thinking and a broad set of possibilities as well as enhances organizational capacity to prepare for crises (Cirka and

Corrigall 2010). Taking into account different features of metaphors, some of them turn out to be especially outstanding in the discourse on food risks. For example, metaphors facilitate the understanding of novel or difficult concepts since they use well-known domains, easily perceivable by the general public (e.g., Bielenia-Grajewska 2009). The most popular metaphoric domains used in food-related communication are the ones of war, journey, and illness. The selection of metaphor domains depend on the result one wants to achieve. For example, if one wants to stress the prerequisite to be active in the face of food risks, then the warfare domain is used to highlight the necessity to fight with food-related hazards. Thus, consumers/patients are pictured in an active way, being able to respond to dangers. It should be stressed, however, that a war metaphor can also be used to show the power of food risks. For example, such verbs as *invade*, *attack*, and *fight* may stress the danger related to food risks (Bielenia-Grajewska 2014). Apart from metaphors, there are also other linguistic tools that facilitate food risk communication. One of them is the notion of numbers. Presenting real numerals in food-related discourse may make the content more appealing among the target audience. For example, information on the number of victims or people infected due to food poisoning may show the real danger. Additionally, the same figure can be presented by the use of numbers, percentage, or fractions. In this case, different numerical representations can evoke different reactions among stakeholders. For example, 100,000 victims can be perceived in a different way than 0.5% of an affected population, although they may concern the same health situations. Another important role is played by adjectives. Thus, the message on threats related to comestibles can be strengthened by such attributes as *dangerous*, *fatal*, or *lethal*. Moreover, information on food-related risk may be supported by quoting some scientific investigations, researchers, food authorities, or well-known scientific journals. A next crucial notion as far as the linguistic layer of food risk communication is concerned is the ability to tailor messages to the needs of target audience. Thus, the type of stakeholders should be taken into account,

by respecting their abilities to encode messages. This aspect entails not only the type of words and the tone of messages but also such paralinguistic features as the color and size of fonts. Moreover, any texts on food risks often entail the presence of some visual elements that may determine the perception of written information among various readers. The application of drawings or photographs to text messages may strengthen or weaken the perception of the text itself. For example, the discourse on food-borne diseases is often accompanied by some pictures of animals or vegetables (depending on the type of food topics), people analyzing stool samples in laboratories, or dishes made from the selected food products. Since the picture of a healthy animal evokes different emotions than the visual representation of creatures suffering from some diseases, the selection of illustration may be used to calm or frighten the readers of texts on food risks.

Summary

Food risk communication is a multidimensional and multifactoral concept. It encompasses diverse food-related risks that are connected with all stages of food preparation and consumption and all types of stakeholders from the alimentation sector. Taking into account the tools of food communication, there are various linguistic and nonlinguistic elements that facilitate the understanding of food risks among diversified public. The way they are used determines the perception of food risks among various stakeholders. As has been discussed, there are different food risks, and the way they are perceived and comprehended by the interested parties is determined by those responsible for food risk communication.

Introduction

I will apply dietetic measures for the benefit of the sick according to my ability and judgment. *The Hippocratic Oath*

Although the word “diet” had a wider meaning in ancient Greek than it has today, it certainly included the choice of food. This quote from the Hippocratic Oath confirms the important role for our health that has been ascribed to food for at least 2500 years. Today the public is confronted with a bewildering mass of information about connections between food and health. Eating too much is unhealthy, but eating too little as anorectics do is equally harmful. There is a long list of (usually tasty) foodstuffs that are subject to health warnings and a similarly long list of (not always equally tasty) foods that are recommended. And then there are all the additives and pesticides,

and other food risks like aflatoxin and Creutzfeldt–Jakob disease. It is not easy to orient oneself in this morass of food risk information.

Before turning to the ethical issues surrounding food risks, this entry will provide a résumé of current knowledge about food risks. For that purpose, a distinction will be made between four classes of food risks. Food risks can refer either to the total energy intake or to specific foodstuffs. They can also refer either to excesses or deficits. Combining these two distinctions provides the four categories shown in Fig. 1. The upper row contains the two risks referring to the total intake of food, as measured in an energy unit such as calories: overweight and underweight. On the bottom row, the other two types of food risks are found: excesses and deficiencies of specific food components.

Specific excesses can be divided into two sub-categories. Some potential ingredients should be avoided altogether, such as solanine (a toxic compound found in green potatoes) and paraquat (a toxic pesticide). Others are harmless or even beneficial in small amounts but toxic at higher levels. A classic example is vitamin A poisoning that may result from a diet rich in liver from some wild animals or from abundant intake of cod liver oil or vitamin supplements. The high frequency of hip fractures among elderly people in some European countries may be due to overconsumption of vitamin A (Lips 2003). However, on a global scale, vitamin A deficiency is still a much larger problem.

As a further complication, the effects of reducing a foodstuff depend on what it is replaced by. Hence, although saturated fat is a risk factor

	Too much	Too little
Food in general	Overweight	Underweight
Specific foodstuffs	Specific excess	Specific deficiency

Food Risks, Fig. 1 The four major categories of food risks

for ischemic heart disease, reductions in saturated fat do not seem to be beneficial. The reason is that people who cut down on saturated fat tend to eat more carbohydrates instead (Lim et al. 2012).

Global Risk Estimates

Causal connections between nutrition and health are difficult to determine, since effects may be delayed and since it is difficult to isolate the effects of a single food component. The Global Burden of Disease Study 2010, GBD 2010, provides a summary of the health effects of a large number of risk factors on a global scale (Lim et al. 2012). Its data for diet-related factors will be summarized in the two following sections. The calculated global number of excess deaths from each risk factor will serve as a numerical estimate of the magnitude of the risk. Since risks differ between populations and between persons, these estimates do not correspond to individual risks. Regional data, of which some will be given below, are somewhat less inadequate for that purpose.

These estimates only include risk factors for which data of sufficient quality are available. Other dietary risk factors than these may have important health effects are not yet known.

Underweight and Overweight

High body mass index (3.37 million deaths/year). Obesity or overweight is measured in terms of the body mass index that is obtained by dividing the person's weight in kilograms by the square of her height in meters. It is usually assumed that a BMI of 18.5–25 kg/m² corresponds to optimal weight. In this study, the “most healthy” BMI for comparison purposes was set at 21–23 kg/m². Obesity is associated with substantially increased risk of a large number of diseases, including diabetes, ischemic heart disease, and several types of cancer.

A similar estimate for the year 1990 showed a smaller number of deaths due to high body mass index (1.96 million/year). Obesity is a growing problem not only in rich countries but also in

countries such as India where malnutrition and food shortage is still a problem for significant parts of the population (Sarkar et al. 2012).

Obviously obesity does not depend on high energy intake alone but on the balance between energy intake and energy expenditure (exercise). For the present purposes, however, it can be counted as a diet-related disease, not least since lasting reduction in food energy intake is an important component of all adequate treatment programs for obesity.

Childhood underweight (0.86 million deaths/year). Childhood underweight increases the risk of various infectious diseases including malaria that terminate the lives of starving children. The corresponding estimate for 1990 was much higher (2.26 million/year). It should be emphasized that although the number of children dying from starvation has decreased substantially, lack of food is still a major cause of death in many countries, in particular in sub-Saharan Africa.

Too Much or Too Little of Special Foodstuffs

Diet high in processed meat (0.84 million deaths/year). Processed meat is smoked, cured, or salted, or contains chemical preservatives. This includes sausages, bacon, and ham. The major health risks are colon and rectum cancer and diabetes.

Diet high in red meat (0.04 million deaths/year). Red meat, as the term is used here, includes beef, pork, lamb, and goat but excludes processed meat, poultry, and fish. The major health risks are colon and rectum cancer, diabetes, and ischemic heart disease. As the figures show (non-processed), red meat appears to be a much smaller risk factor than processed meat.

Diet high in sugar-sweetened beverages (0.30 million deaths/year). Soft drinks have been shown to give rise to diabetes mellitus and to obesity with its associated maladies such as cancers and cardiovascular diseases.

Diet high in trans-fatty acids (0.52 million deaths/year). Trans fat (unsaturated fat with *trans*-isomer fatty acid) occurs in nature, but most of the trans fat consumed is created through

processing of vegetable oils. Trans fat is primarily used in fast food and bakery products. It has also been used to replace animal fat in products for vegetarians. It has been shown to give rise to ischemic heart disease.

Diet high in sodium (3.10 million deaths/year). Sodium (in practice sodium chloride, i.e., common salt) is an essential nutrient, but excess consumption increases blood pressure which leads to enhanced risk of several types of cardiovascular disease including ischemic heart disease. High intake of salt also increases the risk of stomach cancer.

Insufficient breastfeeding (0.55 million deaths/year). Breastfeeding contributes to developing the child's immune system. Babies who are insufficiently breastfed run increased risks of infectious diseases including diarrhea.

Maternal and infant iron deficiency (0.12 million deaths/year). Maternal iron deficiency leads to anemia also in the child. It contributes to both maternal and infant mortality.

Vitamin A deficiency in children (0.12 million deaths/year) increases the prevalence and severity of infections, including measles and intestinal infections. It is also a major cause of blindness.

Zinc deficiency (0.10 million deaths/year) increases the prevalence and severity of diarrhea and pneumonia.

Diet low in fruits (4.90 million deaths/year). Fruit consumption has been shown to decrease the risk of several types of cancer and cardiovascular disease including ischemic heart disease and stroke. The large number of deaths/year associated with low intake of fruits depends both on the substantial positive health effects of fruit and on the large number of people who eat little or no fruit. Low intake of fruit is the only dietary risk factor in this study with a large difference between men and women. The number of deaths/year attributed to it was 1.5 times higher for men than for women. There are two major reasons for this difference: men eat less fruit than women and they are more often victims of cardiovascular disease.

Diet low in vegetables (1.80 million deaths/year). The health risks of low vegetable consumption are essentially the same as for fruits, namely, cancer and cardiovascular diseases. The large

number of deaths/year is also explained in the same way as for fruits.

Diet low in whole grains (1.73 million deaths/year). Whole grains mean those cereal grains that contain cereal germ, endosperm, and bran in their natural proportions. (In refined grains only the endosperm is left.) Common sources are the whole grain variants of cereals, bread, pasta, and rice. A diet low in whole grains is associated with diabetes, ischemic heart disease, and cerebrovascular disease.

Diet low in fiber (0.74 million deaths/year). Fibers from all sources, including fruit, vegetables, legumes, and grains, decrease the risk of colon and rectum cancers and ischemic heart disease.

Diet low in nuts and seeds (2.47 million deaths/year). Consumption of nuts (also in the form of peanut butter) has been shown to have a protective effect against ischemic heart disease.

Diet low in milk (0.10 million deaths/year). Milk has been shown to decrease the risk of colon and rectum cancer (irrespective of whether it is non-, low-, or high-fat milk).

Diet low in calcium (0.13 million deaths/year). Calcium has a protective effect against colon, rectum, and prostate cancer. Milk, cheese, and other milk products are the major dietary sources.

Diet low in seafood omega-3 fatty acids (1.39 million deaths/year). The most important dietary sources of omega-3 fatty acids are cold water oily fish, such as salmon and herring. The effects of these substances are still under debate, but this study accepts evidence of positive effects on the risk of ischemic heart disease.

Diet low in polyunsaturated fatty acids (0.53 million deaths/year). The major part of dietary polyunsaturated fatty acids is omega-6 fatty acids. They are present in seeds, nuts, and vegetable oils such as palm, soybean, rapeseed, and sunflower oil. Studies have shown that replacing saturated fatty acids by polyunsaturated ones reduces the risk of coronary heart disease (Jakobsen et al. 2009; Mozaffarian et al. 2010). However, these results are controversial since some researchers claim that omega-6 fatty acids have negative health effects.

Summary of the Evidence

The evidence reported above can be summed up in the four categories introduced in Fig. 1. The total number of lost deaths/year due to food risks is estimated at 23.71 million and distributed as follows between the four categories:

- Overweight: 3.37 million deaths/year (14%)
- Underweight: 0.86 million deaths/year (4%)
- Specific excesses: 4.80 million deaths/year (20%)
- Specific deficiencies: 14.68 million deaths/year (62%)

It should be noted that alcohol consumption has not been included in this summation since alcohol is not usually considered to be food. If it is included, then 4.86 million deaths/year should be added to the “specific excesses,” yielding a sum of 9.66 instead of 4.80 million deaths/year.

Food risks differ widely between different parts of the world. Regional information is only available in terms of DALY loss. DALY (deaths and disability-adjusted life years) is a measure constructed as a weighted sum of years lost and the estimated loss derived from years lived with disability. Table 1 shows how much the most important food-related risk factors were estimated to contribute to the global burden of disease in 1990 and 2010, measured as DALY loss. Hence in 1990, childhood underweight contributed 8% of the global burden of disease whereas in 2010 it contributed 3%. The remarkable changes from 1990 to 2010 are mostly due to economic and social progress in the third world. Table 2 exhibits the corresponding information for some of the world’s regions in 2010. As the table shows, the food risk pattern differs drastically between different parts of the world, with sub-Saharan Africa and Northern America as the two extremes.

Many details in these tables are uncertain, but the general picture that they display represents the currently best available information about food risks in the world. They therefore provide an adequate starting point for a discussion of food risks, seen as public health problems. Food risks on an individual level may of course deviate

Food Risks, Table 1 Major contributions of food risks to the global burden of disease in 1990 and 2010, as measured in DALYs, a weighted sum of years lost and the estimated loss from years with disability. The percentages indicate how much of the total burden of disease a risk factor contributes to. The risk factors included are those among the top 20 risk factors for the respective year that are food-related

Whole world 1990	Whole world 2010
8% childhood underweight	4% too little fruits
5% too little breastfeeding	4% high body mass index
3% too little fruits	3% childhood underweight
2% too little iron	3% too much sodium
2% high body mass index	2% too little nuts and seeds
2% too much sodium	2% too little iron
2% too little nuts and seeds	2% too little breastfeeding
2% too little vegetables	2% too little whole grains
2% too little Vitamin A	2% too little vegetables
1% too little whole grains	1% too little omega-3 fat
1% too little zinc	
1% too little omega-3 fat	

Food Risks, Table 2 Major contributions of food risks to the burden of disease in 2010, in different regions, measured as in Table 1. The risk factors included are those among the top 20 risk factors in the respective region that are food-related

China	South Asia (India, Pakistan, etc.)
9% too little fruits	4% childhood underweight
5% too much sodium	3% too little fruits
4% high body mass index	3% too little iron
3% too little whole grains	2% too little breastfeeding
2% too little nuts and seeds	2% too little nuts and seeds
2% too little vegetables	2% too much sodium
1% too little fiber	1% too little whole grains
1% too little omega-3 fat	1% too little vegetables
1% too little iron	1% high body mass index
	1% too little omega-3 fat
Brazil and Paraguay	Bolivia, Ecuador, and Peru
7% high body mass index	4% high body mass index

2% too little omega-3 fat	1% too little whole grains
2% too little whole grains	1% too little fiber
1% too little fiber	1% too little polyunsaturated fat
1% too much soft drinks	
1% too little polyunsaturated fat	

substantially from this picture and are best determined by a competent physician.

Ethical Issues

Historically anxieties about food have focused on two types of problem: lack of food and food contamination (Scholliers 2008). The solutions to these problems are simple, at least in principle:

produce and distribute more food and remove the contaminants. Although both types of problem persist, the picture is now dominated by two other types of problems: excess food consumption and improper balance between foodstuffs. The solutions to these problems are much less straightforward, since in both cases individual behaviors need to be changed.

It is important to recognize that food choices depend on much more than health considerations. The cost of food is a decisive factor for the vast majority of consumers. Social, religious, and cultural customs have a large role and so have family traditions. Increasingly, food choices reflect ethical standpoints such as vegetarianism, environmental concern, support for animal welfare, and solidarity with exploited farm workers. Any attempt to promote a more healthy diet will have to take the influence of non-nutritional preferences into account.

The major ethical problem facing dietary reform is that of paternalism, i.e., acting against people's will in what one believes to be their own interest. Urging a person to eat less or differently is an interference in her life, undertaken for her own good. Such interventions are commonly assumed to be both illiberal and disrespectful. However, there are two reasons why the paternalism problem in food risk policy may be less serious that it is often believed to be.

First, people do not make food choices only for themselves but also for their family and guests. When parents shape the tastes and food habits of their children, they also create conditions for their future health. Recommending parents to improve their children's diet is certainly an intrusion into family life, but it is not a paternalistic one (Hansson 2005). If the health of new generations is taken to be a national concern, then governmental and other public measures to promote healthier diets may be justified.

Second, an individual's food choices are much influenced by social and economic factors beyond her control. For instance, it would be misguided to see the current obesity epidemic as nothing more than the aggregate effect of a large number of individual choices to eat more. It is "extremely difficult to believe that people who are morbidly obese and who experience the social ostracism that goes along with it (not to mention the social

inconvenience of just finding nice clothes that fit) want to be that way” (Banja 2004, p. 43). A more credible explanation is that fattening food is better tasting, more accessible, more promoted, and less expensive than healthy food (Schwartz and Brownell 2007). This, of course, is a situation amenable to change through social reform. From an ethical point of view, such reform has the advantage of being less intrusive into private life than health campaigns directed at individuals. On the other hand, it may have the disadvantage of interfering more with corporate freedoms.

Food prices are influenceable and in most countries already much influenced by taxes, subsidies, and trade policies. The fact that healthy food is more expensive than unhealthy, energy-dense food is in all probability an important factor contributing to the obesity epidemic (Adler and Stewart 2009). In many cases, agricultural policy has contributed to price relations that inhibit healthy choices. The European Union’s common agricultural policy has kept up prices of fruits and vegetables by destroying parts of the production. In 1993 this led to the destruction of more than half of French apples, 70% of Italian pears, 50% of Greek nectarines, 50% of Spanish clementines, and 97% of Spanish lemons (Lobstein 1998, p. 84). Poland’s decreased mortality in coronary heart disease in the early 1990s has been attributed to reduced subsidies for animal fats that led to replacement of dietary saturated fats by polyunsaturated fats (Zatonski and Willett 2005). The unintended positive health effects of these economic and agricultural policies stand in stark contrast to the inefficiency of other countries’ attempts to reduce coronary mortality through health policies operating with education and behavior change (Lock and McKee 2005). In Canada, policies maintaining high prices for poultry have prevented healthful replacement of red meat by poultry meats (Cash et al. 2006, p. 623).

Three Examples

The following three examples will serve to exemplify the ethical situations surrounding different types of food risks.

Vitamin A deficiency is common among children in developing countries. In recent years, the frequency of this deadly disease has been substantially reduced through interventions that have largely been funded by foreign aid agencies and charities. The introduction of carotene-rich sweet potatoes, fortification of sugar with vitamin A, and vitamin A supplementation for young children are among the measures that have been successful (Boy et al. 2009). From an ethical point of view, these are obviously commendable interventions. The victims of this food-related disease are small children, and if there is any paternalism involved in what it takes to save them, then that is about as unproblematic as any paternalistic intervention can be. The major ethical problem in this context is that a substantial number of children in need of vitamin supplementation do not yet receive it.

Trans-fatty acids have been introduced into industrially produced food for technical reasons. Trans fat replaces other, healthier fat products. It does not taste differently, and therefore a ban on trans fats affects producers rather than consumers. Such a ban falls in the same category as hygiene standards for food manufacturers and the prohibition of poisonous food additives. Although some voices have been raised against prohibition of trans fat, the concern has usually not been the ban itself but whether it could open up for interventions against unhealthy foodstuffs that consumers may wish to choose. In itself, a ban of trans fats appears to be ethically unproblematic (Resnik 2010; Rubel 2010).

Soft drinks now comprise almost 25% of the daily energy intake of American teenagers. The colloquial expression “empty calories” seems to be adequate in the sense that consumption of soft drinks does not decrease energy intake through other foodstuffs. The strong association with diabetes and obesity only holds for sugar-sweetened soft drinks, not for the diet variants (Caballero 2007; Vartanian et al. 2007). However, soft drink producers strongly oppose any measures that would reduce the consumption of their sugar-sweetened products. There are strong indications that a “sugar tax” would have considerable positive health effects, but political support is weak (Brownell et al. 2009; Wang et al. 2012). A major reason for political inertia seems to be that such

taxes are perceived as paternalistic. However, corresponding taxes on tobacco products now have comparatively strong support. Arguably, the pros and cons of this and other potential anti-obesity policies will have to be reassessed if child obesity does not recede in response to ethically less controversial measures such as education and public health campaigns.

The last of the three examples is the one that is most representative of the type of future ethical challenges that can be expected in food policies. Due to the changing nature of food risks, food policy increasingly involves difficult ethical choices between public health and the public's free access to unhealthy food.

Summary

Overweight is a growing problem, also in developing countries, and it now kills more people than underweight. Excess of sodium (salt) and lack of healthy foodstuffs such as fruits, vegetables, whole grains, and nuts are other important contributors to the global burden of food-related risks. In poor countries, a healthy diet is still beyond the economic means of large segments of the population. Even in the rich industrialized countries, the lower prices and greater availability of unhealthy food contributes substantially to the obesity epidemic. In public health policy, a major problem is to find ways to promote healthy food choices without interfering unnecessarily in the private sphere of people's everyday lives.

Food and culture; Food practice; Moral food; Religious food

Introduction

The study of ritual food practices and morality is, fundamentally, rooted in religious practice and belief. Methodologically, anthropology and sociology are best suited for analyzing ritual actions, intentions, and the boundaries of practitioners' moral or ethical motivations. Religion becomes a central component of ritual actions involving food preparation (cooking) and consumption (eating) when a higher power or supernatural authority is intentionally made part of the ritual food process. In this way, cooking and eating take on meaning beyond nutritional and physical sustenance, becoming modes for interacting with the spiritual or transcendent. There are three fundamental ways in which this occurs. First, an individual or community chooses a certain type of food as a sacramental or sacrificial source of nourishment. Second, a specific food is avoided or considered taboo and is forbidden in ritual food practice. Third, fasting or abstinence from eating a certain food, or all foods, is undertaken as a form of

negative ritual food practice. In each instance, ritual actions are performed which designate the significance of the foods that are eaten or avoided, usually with the goal of religious merit or atonement in mind.

History

The study of food and ritual began in earnest with the advancement of sociological and anthropological methods to understand foreign cultures and their ritualized behaviors in the early to mid-twentieth century. This study of ritual, implemented primarily by Western intellectuals, was fuelled by an ever-increasing globalized sense of the world and its inhabitants, albeit it often an ethnocentric one. Ritual practices (what will be broadly defined here as recurring spiritually motivated and intentional practices) were analyzed for content, efficacy, and outcome in a way that they had not previously been studied. Although food practices were not the only ritualized actions under investigation at this time, they were (and remain) central to sociological and anthropological studies of culture. Food, a fundamental aspect of life, is a universal cultural topic, as all people eat to survive, but at times have different interpretations of what types of food it is appropriate or not appropriate to eat. The designation between food that is acceptable and that which is not typically transcends the edible and inedible and is determined by some system of moral or ethical classification.

Sociologist Émile Durkheim demonstrated this distinction in his early twentieth-century study of religious life in which he noted that many of the indigenous communities that he analyzed had a collective self-image rooted in a totem figure, usually an animal (Durkheim 1995). The totem animal, as reflective of the communal consciousness, took on great power and meaning, and it became taboo to eat those animals that were sacred to the community. As sociological and anthropological approaches shifted away from the “armchair” and into the field, scholars like interpretive anthropologist Victor Turner turned their focus toward the ways in which religion

and ritual could develop into “symbolic system [s]...that both express and shape social reality” (Morris 2006). In this reciprocal model, food practices become a means for understanding culture while also impacting how cultures view themselves.

A student of E.E. Evans-Pritchard, British anthropologist Mary Douglas is among the best-known scholars of food and ritual in the twentieth century. Douglas, striving to find cross-cultural meaning in dietary practices, turned to food and dirt as symbols of social and spiritual purity and defilement (Douglas 1966). This social system of food classification recalls Durkheim’s understanding of totem and taboo, in which the totem animal is to be avoided as food, while other animals are acceptable sources of nourishment.

The study of food and ritual continues to gain momentum through the work of anthropologists like Gillian Feeley-Harnik and religionists like Wade Clark Roof (Feeley-Harnik 1995; Roof 2000). In her work on food and anthropology, Feeley-Harnik notes the value of earlier studies of food and ritual, concurring with Claude Lévi-Strauss and Douglas that it is not enough when studying cultures to reduce their food practices and consumption to mere cultural symbols (Feeley-Harnik 1995). Food practices are instead deeply intertwined with other innate human actions like sex and language and, like these, can be performed in ways that are interpreted as being acceptable or taboo depending upon a culture and what is socially acceptable in it. Roof’s study is one that applies theories of ritual action to the cultural role of barbeque in the modern-day southern United States. For Roof the widespread prevalence of barbequing pork in the south has made the pig a kind of southern totemic figure, one that permeates local food culture from marketing to communal gatherings and is thus ritually prepared (Roof 2000).

Food Ritual Analysis: Ethical Parameters

Whether symbolic or actualized, ritual food preparation and consumption are often ethically imbued. This happens in two ways, as moral

standards are either projected onto the community by outsiders who observe them or are established within the community itself. Instances of these ethical parameters for ritual food practices can be applied to all three categories for ritual food analysis: (1) food as a sacramental or sacrificial source of nourishment, (2) the avoidance of specific foods as forbidden or taboo, and (3) fasting or abstinence from eating a certain food, or all foods, as a form of negative ritual food practice.

Sacramental Nourishment

Indigenous Traditions

Sacramental or sacrificial food practices are performed the world over, as individuals and communities strive to connect with, or even to imbibe the divine. These practices can be found particularly in indigenous traditions that have totem animals and in the Eucharistic practices of Christian churches. When a totem for a community is an animal (for instance, in an aboriginal community that identifies with and treats as sacred the kangaroo), contact with the totem animal may be taboo or off-limits because of its elevated position, or the animal may (rarely) be sacrificially eaten so that the community might ingest some of its power (Freud 1946). When the totem is eaten, it is important that it only be ingested by members of the community, as its sacred power is believed to be connected to them alone. For most communities, a collective identity is crucial for their survival as a unit, and the ritualized eating of their sacred animal becomes one way in which this group character is maintained. By performing the rituals associated with the cooking and eating of the totem animal, the community is able to reach into their shared past, participating in and perpetuating their own sacred myth (Eliade 1987).

Christianity

Many of the same principles hold true in the Christian tradition, as the Eucharistic meal is considered by participants to be powerful and is a way for individuals to collectively participate in and affirm their place within the church community. For Christian churches, the sacramental food

(bread and wine) has different meaning depending upon which denomination one participates in. In the Roman Catholic Church, the ritual practice of the Eucharist is considered by members to be a process of transformation. The doctrine of transubstantiation means that for Catholics the communion elements of bread and wine are changed by the ritual actions of the priest, converting these elements in essence to the actual body and blood of Jesus Christ. The belief that the food elements are literally transformed into flesh and blood presents many ethical issues for the standards that determine the ways in which these food elements are handled and distributed. According to the tradition, this means that only a priest has the authority and ability to preside over the ritual process, that the bread and wine are not more than mere food and drink until after the ceremony is performed, that after being transformed the elements cannot be abused or discarded (other than to be ingested), and that only a select population (baptized, practicing Catholics) are permitted to touch and eat them. The ritual food and drink are only supposed to be consumed by those who have a clear conscience and with the proper spiritual intention.

As sacred food, the Eucharist is also central to ritual life in Protestant Christian churches. A historical point of contention between the Eucharistic practices of the Roman Catholic Church and its Protestant sister churches rests on the limitations of who can participate in the ritual. Protestant churches generally hold that the Roman Catholic Church's approach to the Eucharistic ritual is not in-line with the message of inclusivity central to the Christian tradition. For Protestant churches, this means a necessary ethical shift from the concept of transubstantiation in the ritual process to one of consubstantiation, or the belief that the presence of Jesus Christ in the Eucharist is more symbolic than literal. This consubstantiative approach to the Eucharistic meal led to a number of differences in ritual, including the ability for ordained women to perform the rite, for all believers to participate in the meal (and not just baptized Protestants), and to less formalized preparation, treatment, and storage of the food elements.

Taboo Foods

Judaism

For a number of the world's religious traditions, there are also foods that are designated as being taboo or forbidden. In Judaism, Islam, and eastern traditions like Hinduism and Jainism, specific foods are off-limits, and ritualized food preparation practices are put into place to ensure ethical consumption. As Douglas noted, in the Jewish tradition, special attention is paid to the dietary laws found in the Old Testament book of Leviticus (Douglas 1966). These laws are the foundation for what is considered to be kosher, or *kashrut*, and therefore morally acceptable for consumption. In order for foods to be pure, rather than defiled and unfit to eat, the process of their production must be certified by a rabbi or approved organization. In this religiously systematic way, their production becomes ritualized.

For foods to be considered kosher, their production and content follow a strict set of ethical criteria. Kosher animal products must be in good health before being slaughtered and have to be killed in a humane way. The blood from these animals has to be completely drained before they are able to be cooked and eaten. There are restrictions as to which foods meat and dairy can be mixed with, and they are not to be consumed together. While some foods made by non-Jews are permissible, those following a strict kosher diet try to only eat foods that have been prepared within the dietary parameters of the tradition. Food choice, production, preparation, and consumption become religiously ritualized through the kosher diet, which is practiced in different degrees by Conservative, Reform, and Orthodox Jews.

For Jews, the moral and ritual process of food production is carried beyond the butcher shop or factory and into the home. In the Jewish tradition, domestic ritual meals take place each week on *Shabbat*, and several times a year as a way of reaffirming one's faith and place within the Jewish past and wider Jewish community. Perhaps the best example of this type of food ritual is the observance of Passover, in which Jews recall, in part through a ritualized meal, the Old Testament

Exodus story of the freedom of the Israelites from slavery in Egypt. Symbolic foods are eaten as part of this Passover *Seder* meal, including unleavened bread called *matzoh*, bitter herbs, lamb, and wine, with each item standing for a specific part of the Israelites' story.

Islam

In some ways similar to Jewish kosher dietary laws, many adherents of the Muslim tradition follow the food restrictions of *halal*. Halal dietary laws are firm and include the avoidance of pork and alcohol, in addition to not being able to eat the blood of any animal, and having to eat only humanely slaughtered animals. Like kosher dietary laws, halal food standards for production are highly organized and require certification to ensure that foods are spiritually and ethically pure for the Muslims buying them. In both the Jewish and Muslim traditions, all ingredients for processed food items have to be carefully chosen and labeled to ensure that even food additives are within the limitations of what can be safely and morally eaten.

Beyond physical production and ingredients, certified kosher and halal foods must be prepared with the right spiritual intentions in mind. In these traditions and many others, dietary laws are taken from divine scripture (the Qur'an in this case) and are believed to be directions for eating and food preparation as given directly to humans by God. Both methods of dietary guidance are therefore aimed at beneficial physical and spiritual nourishment. This is why so much attention is paid to the process of production. For a food item to remain ritually pure, it must be made with the least bit of harm and a heightened awareness of source.

Hinduism/Jainism

In the Hindu tradition, food has an "essence" – spiritual and social meaning beyond nourishment (Khare 1992). In India, food has traditionally been connected to caste as well as ritual life. In a tradition in which one's *dharma*, or moral duty, is central, eating in Hinduism became an act of adhering to cultural and thus spiritual order. Hindu dietary laws can be traced to holy books within the tradition. Food is a central topic in the

Laws of Manu, an early Indian text outlining the laws that governed all aspects of cut- repetitive life. Acceptable and taboo foods are outlined for the "twice-born" man (males born into the three higher Hindu castes) so that he can successfully navigate through dietary rituals and restrictions in order to uphold his dharma and maintain social and religious harmony (The Laws of Manu 1991). Special attention is also given to ritual actions that must be performed when some foods (certain birds and animals in particular) are prepared to be sacrificially eaten.

Like kosher and halal dietary laws for what is acceptable and what is taboo (based on spiritually ritualized food preparation practices), in Hinduism, there are certain foods that almost all adherents avoid, while there are others that only the strictest followers do not eat. For instance, many Hindus completely avoid eating beef out of religious and cultural respect for the cow. This practice extends for some into total vegetarianism, rooted in the belief that killing animals for food results in a bad karmic, or cumulative moral condition based on behavior or action. In the Hindu tradition, there is also an emphasis on treating all foods ritually because everything in life can potentially be considered a sacrificial offering to the divine (Bhagavad Gita 1986). To offer food to divinity is to communicate with the transcendent in a way that connects the sacred and mundane. In approaching all food practices as sacred, Hinduism invites adherents to partake in a primordial ritual of spiritual and physical nourishment that reaffirms belief in a natural hierarchy between human and divine (Morris 2006).

The Jain tradition, with its roots in earlier Indian spirituality, takes an even stronger stance on nonviolence, or *ahimsa*, with regard to what foods it is appropriate or not appropriate to eat. Jain ascetics take this to the extreme, avoiding killing in their consumption to the greatest extent possible. The men and women who take up Jain monastic life vow first to only eat that which is given to them, so as to not personally harm any creatures, large or minute, in the process of food preparation. Jain ascetics are vegetarians, trying to avoid accruing bad karma by eschewing meat and root vegetables (foods in which the entire plant

dies when harvested), and only consuming strained water in order to minimize their effect on even the smallest bugs that might pass undetected through their diet. In sharing food with ascetics, the laity engage in the ritual process and are also able to work off their karma. Sharing food with ascetics thus becomes repetitive a mutually beneficial spiritual act. For the Jain laity, dietary practices are not as strict, but food remains sacralized. Though lay eating practices are not as ritualized as those of the ascetics who strain their liquid and accept food offerings, Jain lay people must navigate through issues of nonviolence in their worldly lives. As part of their spiritual commitments, Jain laity are not even permitted to take jobs that might cause harm, including butchery.

Fasting Rituals

Fasting, or abstaining from eating specific foods or all foods, is a cross-cultural phenomenon in the spiritual lives of many. To fast is to sacrifice eating, usually with the goal of some degree of spiritual purification. Although the practice of fasting fundamentally means an avoidance of food, it is nonetheless an aspect of ritualized food practice. Fasting in world religions typically takes place during periods of spiritual reflection or atonement like Passover (Judaism), Lent (Christianity), and Ramadan (Islam) and is by its cyclical nature ritualistic.

Like sacramental and taboo foods, definitions for fasting are different across cultures and traditions. For instance, in her study of the eating habits of medieval women, Caroline Walker Bynum reveals how fasting became a vehicle for piety – in stark contrast to the abundance of Catholic feast days during the period (Bynum 1988). For the men and women who chose to lead contemplative lives in the monasteries and cloisters of the Roman Catholic Church at this time, fasting was a way to strip an already austere life of one of its remaining pleasures (food) so as to show total attention and devotion to God. Fasting is not only a practice of ascetics however but one also undertaken by the laity.

While Protestant Christian denominations do not discourage the practice of fasting as part of religious life, the role of fasting in Protestantism is

historically not as prominent as it is in Catholicism. Fasting in the Roman Catholic Church, whether it is before receiving the Eucharistic elements as a measure of spiritual purification or abstaining from meat and not eating between meals on Fridays as a practice of penitence during the liturgical season of Lent prior to Easter, is a ritualized restriction or avoidance of food for religious purposes. By fasting, the Catholic hopes to bring herself or himself closer to God through self-sacrifice. In the Jewish tradition, fasting is also a spiritual exercise and a means of reparation. Jewish fasting is undertaken in particular on holy days like Yom Kippur (the Jewish Day of Atonement) as an expression of faith. In both Judaism and Christianity, ritual fasting is only required of those who are physically healthy enough to not eat for extended periods of time. Traditionally, rules for fasting are less severe for children, pregnant women, the ill, and the elderly, although these individuals are encouraged to participate in the fasting ritual to the extent in which they are able.

Ritual fasting is one of the five pillars of Islam and is practiced during the Muslim holy month of Ramadan, which commemorates the time in which the Qur'an was revealed to be the Muslims' Holy Scripture. Adherents fast from dawn to dusk each day for the entire month as an exercise in self-purification. Fasting is also part of the ritual lives of religious practitioners in eastern traditions. While extreme fasting is sometimes assumed by *sadhus*, or Hindu holy men, Buddhist monastics take a different approach. In the Buddhist tradition, it is believed that the historical Buddha, Siddhartha Gautama, in the sixth-century B.C.E. took up a life of grueling asceticism in order to become enlightened. In the process, he discovered a fundamental doctrine of Buddhism, the "middle path" or "middle way," in which a life of overindulgence or a life of excessive asceticism is not conducive to achieving enlightenment. Rather, the Buddha taught that it was necessary to live somewhere in between. This "middle path" applies to ritual food practices in Buddhism. Ascetics in the tradition are often given their food by the laity (with the laity gaining merit for feeding the monks) and, according to the *Vinaya*, or rules for Buddhist monastic life, vow to only

eat before midday each day and to fast the rest of the time. They eat only what is necessary to be healthy and to survive.

Summary

Ritual food practices are often social and cultural manifestations of spiritual belief and adherence. The three primary categories in which these ritual practices can be consigned are (1) sacramental or sacrificial food practices (like the Christian Eucharistic meal), (2) the avoidance of taboo or forbidden foods (like beef in Hinduism), and (3) fasting or abstaining from food as a form of spiritual reflection and atonement (like Muslims during the holy month of Ramadan). From early studies of ritual food practices a century ago to scholarship of the present day, anthropologists and sociologists have worked to reveal the underlying religious, ethical, and moral implications of ritualized food practices in different cultures. Regardless of tradition, ritual dietary practices can serve as a means for cross-cultural study, as food and eating are significant to all people across time.

[Food regulation](#); [Food risks](#); [Health](#); [Responsibility and liability](#); [Risk assessment](#); [Toxicology](#)

Introduction

The term “food safety” has come to be associated with a variety of technical and regulatory mechanisms designed to minimize the risk of morbidity and mortality associated with human consumption of food. The ethics of food safety comprises philosophical questions that arise in connection with conceptualization of risks tied to food consumption, the assignment of responsibility and liability for precautionary measures and for actualized harms, and interpretive ambiguity that occurs in the performance of regulatory standards and precautionary measures, including enforcement. More broadly, the emergence of food safety as a regulatory and conceptual paradigm is typical of the social, political, and cultural themes that

define late capitalism and globalization. In this connection, contestation over the safety of food has become an element in broader forms of resistance to power relations that exist within the contemporary food system. Following a brief overview of emerging legal regimes, each of these four domains for examining the ethics of food safety is discussed below.

Food Safety and Regulation

Regulation of food processing and handling on grounds of safety dates back to the last decades of the nineteenth century. Legal codes for food safety emerged in part as a response to industrialized processing and food retailing: long-distance shipment of meats and grains, canning, chemical preservatives, the creation of branded foods, and the grocery industry. In each case, technology created new opportunity of adulteration of foods – an age-old problem that had previously been addressed under the legal regime of merchantability and caveat emptor. Louis Pasteur's work on microbial contamination and the development of technical means to control it reinforced a conception of food safety associated with the notion of purity. At the same time, chemists such as Frederick Schlink began to accumulate data on risks of preservatives and additives intended to increase the sensory appeal of processed foods. The net result has been the creation of national and local agencies charged with overseeing various aspects of the food system for the purpose of protecting public health (Vileisis 2008).

Food safety regimes are in fact a piecemeal aggregation of laws and government agencies, mostly created in response to episodes of public outrage. The US Food and Drug Administration was famously created in the wake of Upton Sinclair's colorful (but sickening) portrayal of abuse in the meatpacking industry. Inspection of imported foods often continues to be done by agencies originally formed to regulate commerce and protect local farmers. Legal oversight extended to farming practice in the wake of Rachel Carson's *Silent Spring*, exposing the risks of chemical pesticides, and has grown to

include rules requiring whole food-chain traceability of foods in the wake of mad cow disease and other incidents of contamination in Europe. The Codex Alimentarius is an agency within the Food and Agriculture Organization (FAO) of the United Nations that was initially formed to facilitate international coordination of food safety standards and which now operates in conjunction with the World Trade Organization. Meanwhile, inspection of restaurants or food service facilities remains a responsibility of public health authorities that may operate at a regional or municipal level (Millstone and Van Zwanenberg 2002).

Food Safety Risks

There is an obvious sense in which knowledge of whether foods can be consumed with inordinate risk of injury or death must be very nearly as old as civilization itself. Even in prehistory, humans must have had an implicit recognition of toxic potential. It may have been codified in terms of simple edibility and may have been reinforced by cultural or religious dietary norms. Some have speculated that kosher dietary laws may have evolved in part as a response to food safety risks (Regenstein and Regenstein 2001). The idea of edibility took further shape as an ideal of purity. Pasteur's development of the germ theory bolstered the idea that food safety could be achieved through limiting contamination by microbes. Works such as *100,000,000 Guinea Pigs* and *Silent Spring* further reinforced this way of understanding food safety. The idea that purity and naturalness are bound tightly to safety continues to influence many nonscientists' views on food safety (Thompson 2007).

Within toxicology, risk is conceptualized as function of *hazard* and *exposure*. A hazard is defined by the mechanism that induces harm to an organism. In the case of food safety, for example, it is important to distinguish between the acute toxicity that would be associated with caustic substances, poisons, and some allergens that trigger rapid and extreme inflammatory responses and those that occur either through multiplication of organisms (such as *Salmonella* or *E. coli* O157:

H7) or through accumulation in cells. Carcinogens and mutagens cause harm by disrupting ordinary cellular functions, and both endocrine disruptors and prions are believed to cause harm because their molecular shape triggers disease processes in the body. Toxins in this last class may not exhibit harmful impacts for years.

Exposure concerns the probability or likelihood that hazards will actually materialize. Exposure typically varies according to the amount or degree of physical contact with a toxin (e.g., the dose), but one key area of uncertainty in food safety risk assessment concerns the question of whether a given toxin exhibits a threshold or minimum dose for inducing any harmful effects. Following influential work by Bruce Ames, the view on some mutagens is that purity – or lack of contamination and physical contact – may not be an accurate way to conceptualize risk or to formulate strategic responses to some food risks. Carcinogens – the target of the FDA’s Delaney Clause (see Vileisis 2008) – may occur naturally and become disease agents within a matrix that also contains anti-mutagens capable of offsetting the cellular mechanisms that cause cancer (Ames 1983). Hormesis – a process by which some chemicals that are essential nutrients at low levels become toxic at higher levels – also introduces uncertainty into the quantification of exposures. Such uncertainties in food safety can be exploited by industry-supported risk assessments (Elliott 2011).

Quantified food safety risks are amenable to different ethically based management strategies. The dominant philosophy of industrialized food safety agencies adapts utilitarian cost-benefit reasoning by starting with quantified risk assessments as a measure of food safety value. A food safety decision is viewed as not ethically justified unless based on scientifically measured risk (e.g., a quantitative estimate of hazard and exposure). However, food safety agencies do not generally calculate a trade-off between risk and benefit (though there are exceptions: the US Environmental Protection Agency does take benefits to farmers into consideration when evaluating pesticides). Instead, they adopt the *de minimis* rule: food-borne risks should be as low as is practically

feasible. Emphasis on practical feasibility has led to the widespread use of Hazard Analysis and Critical Control Points (HACCP) as a risk management strategy within the food industry (Gaworski et al. 2006).

The science-based *de minimis* risk approach to food safety has been faulted for relying too heavily on expert judgment. In contrast, an extension of the informed consent principle used to manage risks to the subjects of medical research would call for measures that place ordinary consumers into a better position to apply their own values. Such an approach might rely on labels or values-based standards to provide opportunities for individuals to avoid foods based on whatever considerations they believe to be important. Judgments about safety might here be treated on a par with religious values or political values that relate to food choice (Thompson 2002). Alternatively, some authors have argued for more involvement of nonscientists in risk assessment or in the policy development phase of food safety regulation (Millstone 2009). In a similar vein, social impacts might be incorporated into food safety assessments along with more traditional toxicological hazards (Dreyer et al. 2010).

Safety of genetically engineered crops is the most widely discussed risk issue in the ethics of food safety literature. The debate over “substantial equivalence” is a key point of contestation. Although not strictly a principle of risk management, the doctrine of substantial equivalence was developed as a basis for deciding when genetically engineered crops required a fully developed risk analysis on food safety grounds. The terms and requirements of substantial equivalence are themselves debated in the literature, but the basic idea is that this decision should be based on whether the active protein created by a newly introduced transgene either has appeared previously in foods that are Generally Recognized As Safe (GRAS) or has itself been found safe in previous tests. Advocates have claimed that this test is sufficiently powerful to insure that genetically modified crops are at least as safe as the most genetically similar non-modified variety (Kearns and Mayers 1999). Critics have claimed that reliance on substantial equivalence will fail to detect

inadvertent creation of novel proteins as a result of the process of genetic modification (Millstone et al. 1999).

Many who have opposed the introduction of genetically modified organisms (GMOs) have advanced “the precautionary principle” as the basis of their argument. Developed initially as a principle for the management of environmental risks, the precautionary principle states that lack of full scientific certainty should not be used as a basis for taking precautionary action. In the context of food safety, precautionary reasoning might provide a basis for taking steps to remove or control potential hazards well before the science has addressed some of the uncertainties discussed above. In the case of mad cow disease, for example, a precautionary stance might have provided a basis for steps to regulate beef well before the United Kingdom’s food safety agency decided to do so (Millstone and van Zwanenberg 2001). Applied to GMOs, the precautionary stance justifies a suite of policy responses taken in Europe (Levidow 2001). Gary Comstock has provided an extensive ethics-based discussion of the GMO issue and the precautionary principle in which he concludes that the most obvious ways to apply precaution lead to logical inconsistencies (Comstock 2010).

Responsibility and Liability

There are numerous points in the food supply chain that extends from the primary producer to the final consumer where responsibility for food safety might be distributed. A review of the food safety literature in 2003 showed that many of the most damaging microbial contaminants to food are most effectively controlled during the final stages of food preparation and consumption (Redmond and Griffith 2003). Such findings support wide-ranging educational efforts on appropriate storage and handling procedures and on the role of high cooking temperatures in destroying microorganisms that are the source of many food safety hazards. They can also be used to support the claim that food preparers bear the brunt of ethical responsibility for assuring safe food and

should shoulder the liability when injuries arise. Alternatively, the rise of the regulatory regimes for food safety described above can be taken to imply that the primary responsibility for food safety resides with the state. In either case, the distribution of ethical responsibility might be portrayed as a way for industry to shift the responsibility for safe food away from its own shoulders and to reposition it on other actors in the food system (see Nestle 2002). At the same time, supermarkets and chain restaurants have also been in the process of developing their private standards for assuring the safety of products in their retail outlets. In part as a result of inaction by state agencies and also as response to the decline in consumers’ confidence in science-based regulatory agencies, the private sector has become more involved in the development of technology and enforcement procedures (Hatanaka et al. 2005; Havinga 2006).

Food safety assurance is becoming a profession and food safety professionals are increasingly being placed in positions of internal oversight within food industry firms. Though versed in scientific principles, these food safety professionals must combine a practical understanding of inspection and HACCP procedures with skills of personnel management. They are often at the key juncture where pressures for filling orders and making profits may challenge the performance of sanitary procedures that are crucial for food safety. These individuals occupy a frontline position of responsibility for the protection of public health but may have little status within their company. There is thus a new and as yet not well-studied area of professional ethics associated with this group of employees within the food industry (Mather and McNiel 2006). In this context, ethical responsibility will encompass questions of corruption, fraud, and whistleblowing that have yet to be studied in the scholarly literature.

Similar issues of professional ethics apply to regulators and inspectors in the public sector. The 2006 contamination of powdered milk in China provides a case study. Melamine is a chemical that has been shown to exhibit toxic potential at sufficiently high doses. During a period of rapid

growth in the Chinese dairy industry, producers of powdered milk adulterated the product with melamine in an effort to mask quality deficiencies and to frustrate tests that would have revealed low protein content and general poor quality. The practice was accompanied by bribery of inspectors and high-level officials in the Chinese food safety agency (Pei et al. 2011). Zenobia Chan and Wing-Fu Lai have argued that the melamine incident must be interpreted as an issue of ethics. The failure goes beyond one of law and policy in their view and implies the need for a wider appreciation that achieving food safety and protecting health are responsibilities grounded in ethical norms (Chan and Lai 2009).

Interpretive Ambiguity

While the Chinese melamine contamination case is an example of unambiguously unethical conduct on the part of many actors, the implementation of food safety policy and procedure is in fact fraught with numerous opportunities for differences in interpretation and work style. These ambiguities have practical significance in posing contrasting and sometimes incompatible forms of practice. They can also turn upon points of philosophical and ethical significance. Although national food safety regimes display significant overlap in the description of their elements, structure and policy, the implementation of this framework differs significantly from one nation to another. Some countries are far more responsive to input from nonexperts, while in other countries, any influence from sources other than the scientific community is viewed as political interference in an objective, scientific process (Lodge 2011). Food industry firms that introduce new food safety mechanisms may expect that these procedures will protect them from both legal liability and public censure, yet the plethora of styles and practices that exist for pursuing food safety across the food industry virtually insures that corporations will be viewed as irresponsible actors and as potential threats to public safety (Maloni and Brown 2006).

Even fairly mundane food safety procedures can exhibit philosophically significant patterns of indistinctness and opportunities for ethically based analysis. Although cases such as the Chinese melamine contamination incident suggest that ethics calls for strict implementation of procedures that have no place for compromise, in fact, almost all implementation procedures require judgment. Employee compliance with crucial food safety rules may depend upon managerial supervision that emphasizes education and improvement over compliance. Food safety inspectors display distinct styles in deciding when to “write up” technical violations or to use them as opportunities to help managers or small companies improve their procedures. Food safety, in short, can be envisioned as an opportunity for cooperative collaboration between overseers and practitioners as readily as it can be viewed as an enforcement activity focused on strict compliance. This ambiguity becomes especially significant when the firms in question have relatively little economic power or may represent efforts by individuals who are typically marginalized by larger corporate actors in the food system. While an ethic of food safety requires that public health must not be endangered, there are nonetheless opportunities for improving safety and health by helping private sector actors achieve their business-oriented goals (Buckley 2013).

Food Safety as Culture

The conceptualization of food safety provides an instance of more general social phenomena that have been described as “risk society” by Ulrich Beck and as “discipline and power” by Michel Foucault. Like practices associated with health and sexuality, food has been a target for the emergence of scientific disciplines that regulate or “discipline” a host of individual and social practices. In building disciplinary practice around replicable results and statistical significance, these sciences normalize social practice in a manner that, while perhaps socially beneficial and justifiable, nevertheless excludes and marginalizes activities, traditions, and processes of food

production, preparation, and consumption that have value to some individuals and groups. In this manner, scientific disciplines for defining and implementing food safety become part of a nexus of power relationships in which some individuals and groups inevitably find themselves caught up. In this respect, food safety is typical of key developments in other domains of society that have been studied by Foucault (Zwart 2000).

Beck's work has emphasized how the expansion of science into virtually all quarters of life and the growth in scientific literacy and scientific thinking has actually promoted a level of sophistication and skepticism that has undermined the public's confidence in science-based institutions (Beck 1992). Clearly, food safety stands at the forefront of such "reflexive modernization," as Beck calls it, although the science of food safety has expanded markedly over the last century and public governance institutions have been built upon it. The idea that trust, specifically either in science or in food safety regulatory institutions, is eroding is a frequent theme in recent food safety research (see Almas 1999; Knight and Warland 2005). Paul Thompson has argued that the themes of cultural transformation and risk can be addressed from an ethics perspective utilizing the work of Annette Baier. Here it becomes crucial to tease apart the difference between being trustworthy and being trusted and the question of whether the social relationship is even amenable to trust, in the first place. The types of disciplinary power relationships studied by Foucault are more fruitfully understood through an ethical analysis of resistance, rather than a failure of trust (Thompson 2007).

Summary

Although relatively few philosophers have undertaken systematic studies of ethics and food safety, the topics surveyed above demonstrate that food safety is ripe for more nuanced philosophical scholarship, as well as more development of extended case studies. The field of food safety professional ethics is an especially important example of an area where new studies are needed.

At the same time, the technical complexity of food safety science and toxicology suggests that some of the most useful philosophical work will come out of the philosophy of science (see, e.g., Elliott 2011). While social scientists are developing a strong literature in food safety policy, the creation of a strong literature reflecting the insights and conceptual tools of philosophical ethics largely awaits future developments.

Food Security

Irene Hadiprayitno
Human Rights and the Right to Food, Leiden
University, Leiden, The Netherlands

Synonyms

[Right to food](#)

Introduction

Food security, despite its simple label, is an immensely complex concept, which has been defined in different but similar ways. Some estimate that approximately 200 definitions and 450 indicators of food security exist (Smith et al. 1992). Currently, the common definition applies: food security is a situation that “exists when all people, at all times, have physical and economic access to sufficient, safe and nutritious food that meets their dietary needs and food preferences for an active and healthy life” (FAO 1996).

Food insecurity may occur because of the lack of availability of food, insufficient purchasing power, and inability to produce food and feed themselves at the household level. Additionally, inadequate care, especially for women and children, insufficient health service, and unhealthy environment that are closely connected to inadequate education and other societal factors are also the underlying determinants for food and nutrition status. Food insecurity may be chronic, seasonal, or transitory.

The Evolutionary History of Food Security

Food Security Before the 1990s

As a concept, food security has evolved since it was first developed in the 1970s. Then, the focus was on increasing availability and stability of world food supply to meet the growing demand. In 1981, the Noble Laureate, Amartya Sen, with his groundbreaking thesis on capability changed the focus from availability to food to access to food. Based on the series of studies in India, he argued that to say something about food supply is to say more than just commodity only, but about relationships between persons and that community (Sen 1981). This means that individual food security was primarily dependent on their possibility to access food, labor-based, trade-based, transfer-based, or other entitlement relationships. A shift was therefore made from national level to household/individual level (Maxwell 1996).

The food security agenda in the 1990s was also further broadened by health and nutrition research, which highlighted the fact that reciprocal and synergetic linkages exist between food intake and nutritional well-being (De Rose et al. 1998). The development allowed nonfood causes of food security to be looked into, such as inadequate care – particularly children who need not only sufficient healthy food but also somebody to feed them. Since then, food security is connected with wider goals, such as adequate nutrition or nutrition security, adequate care, and adequate prevention and control diseases. The changes in defining the substantive meaning of food security are to a certain extent reflected in the transformation regarding the ways in which international community addresses the issue of feeding the world.

The World Food Summit's Approach on Food Security

Hitherto there have been three World Food Summits organized by Food and Agriculture Organization (FAO). In the World Food Summit, 13–17 November 1996, Member States adopted the Rome Declaration on World Food Security. The declaration mentions the new formula for

defining food security at global, national, household, and individual levels. It is asserted that “food security is achieved when all people, at all times, have physical and economic access to sufficient, safe and nutritious food to meet their dietary needs and food preferences for an active and healthy life.” This definition is the current working prescription applied on food security.

The Rome Declaration was completed with a Plan of Action that aims to lay the foundations for diverse paths to a common objective of food security. The Plan of Action contains 7 commitment areas with a total of 27 objectives and actions relating to:

- (i) Ensuring and enabling political, social, and economic environment most conducive to achieving food security for all
- (ii) Implementing policies aimed at eradicating poverty and inequality and improving physical and economic access to food by all
- (iii) Pursuing participatory and sustainable policies and practices in high and low potential areas
- (iv) Striving to ensure that trade policies are conducive to fostering food security for all through a fair market-oriented world trade system
- (v) Endeavoring to prevent and prepare for natural and human-made disasters and meet transitory and emergency food requirements in ways that encourage recovery, rehabilitation, development, and a capacity to satisfy future needs
- (vi) Promoting optimal allocation and use of public and private investments to foster human resources, sustainable agricultural systems, and rural development in high and low potential areas
- (vii) Implementing, monitoring, and following up the Plan of Action at all levels in cooperation with the international community

By the end of the World Summit, two important commitments were agreed upon. The first is to halve the number of undernourished people no later than 2015. The second is a commitment “to clarify the content of the right to adequate food

and the fundamental right of everyone to be free from hunger.” As to the latter, a concrete response came from the United Nations, which in the same year adopted the General Comment No. 12 on the Right to Food. As to the first commitment, the ambition was later reaffirmed in the Millennium Declaration adopted by the UN General Assembly in 2000.

Additionally, the Summit has created further discussions on international trade and food security. The recommendation for establishing a Working Group for Trade and Food security was adopted at the 1996 Singapore WTO Ministerial Conference.

In 2001, once again upon invitation of FAO, the second World Food Summit was organized. The Summit resulted, among others, in giving the mandate to FAO to install the Intergovernmental Working Group (IGWG) that was tasked to support the Member States’ efforts to achieve the progressive realization of the right to adequate food in the context of national food security. After series of meetings in the period March 2003–September 2004, the Working Group delivered the final version of “the Voluntary Guidelines to support the progressive realization of the right to adequate food in the context of national food security.” The guidelines give practical directions on 19 topics, based upon three underlying dimensions of the right to food: adequacy, availability, and accessibility.

The third World Food Summit was held in November 2009: the World Summit on Food Security. In the final declaration, the goal to halve the number of people who suffer from hunger or malnutrition by 2015, which was also set during the first World Food Summit, was reaffirmed, and the declaration contained commitments and actions that would lead to food security.

Indicators for Food Security

FAO uses the indicators derived from the definition of food security itself, which include several specific measurements derived from the concepts of availability and access. Utilization is added to clarify the concept of access, by referring to households’ use of the food to which they have access to, and individuals’ ability to absorb

nutrients – the conversion efficiency of food by the body. From the normative content of food security, some scholars propose additional indicators, adequacy and sustainability (Oshoug et al. 1994). Adequacy refers to nutritional adequacy, food safety and quality, and cultural acceptability. Sustainability entails environmental sustainability and social sustainability.

The most common indicators of food security revolve around measures of food consumption (Bouis 1993). A good measure requires data collected at the household level including the household size, age, and sex of individuals, as well as physical size and activity levels.

Another indicator is the use of coping strategies, which suggest that coping behaviors formed a set of patterns that could be monitored in famine situations (Frankenberger 1992). Coping strategies indicators can be decomposed to analyze separately those behaviors that increase the short-term availability of food and rationing behaviors aimed at dealing with outright short-term insufficiency of food (Maxwell et al. 1999).

Advocating the dietary diversity as food security indicator is not something new. In this approach, it is argued that households with low levels of dietary diversity are likely to have low level of consumption per person and low caloric availability. As such, dietary diversity can play a role in identifying the food insecure, monitoring changes in circumstances, and assessing impacts of interventions (Hoddinott and Yohanness 2002).

The Right to Food

What Is the Right to Food?

The human right to food is an older concept than food security. It received international recognition since 1948, with the adoption of the Universal Declaration of Human Rights. Article 25-(1) stipulates that “everyone has the right to a standard of living adequate for the health and well-being of himself and of his family, including food, clothing, housing, and medical care and necessary social service.” The International Covenant on Economic, Social and Cultural Rights, adopted in 1966 and entered into force in 1976,

recognizes in Article 11 “the right of everyone to an adequate *food*, clothing and housing.”

This recognition has repeatedly been incorporated in numerous normative instruments in international law, some of which are binding on states which have ratified them or can be applied as customary law.

Substantive and Procedural Contents of the Right to Food

On the right to food, Article 11 of the International Covenant on Economic, Social and Cultural Rights (ICESCR) stipulates:

1. The States Parties to the present Covenant recognize the right of everyone to an adequate standard of living for himself and his family, including adequate food, clothing and housing, and to the continuous improvement of living conditions. The States Parties will take appropriate steps to ensure the realization of this right, recognizing to this effect the essential importance of international co-operation based on free consent.
2. The States Parties to the present Covenant, recognizing the fundamental right of everyone to be free from hunger, shall take, individually and through international co-operation, the measures, including specific programmes, which are needed:
 - (a) To improve methods of production, conservation and distribution of food by making full use of technical and scientific knowledge, by disseminating knowledge of the principles of nutrition and by developing or reforming agrarian systems in such a way as to achieve the most efficient development and utilization of natural resources;
 - (b) Taking into account the problems of both food-importing and food-exporting countries, to ensure an equitable distribution of world food supplies in relation to need.

The General Comment defines the term “adequate food” more precisely and points out the different types of obligations for Member States resulting from the right to food. In Paragraph 8 of

the General Comment No. 12, the Committee on Economic, Social and Cultural Rights has concluded that the “core content” of the right to adequate food implies ensuring:

The availability of food in a quantity and quality sufficient to satisfy the dietary needs of individuals, free from adverse substances, and acceptable within a given culture; The accessibility of such food in ways that are sustainable and that do not interfere with the enjoyment of other human rights.

Like any other human rights, the state is the duty-bearer of the right to food. There are two ways on how state parties should approach their obligation. First is that state parties must act *immediately* for instance in relation to non-discriminatory measures and to mitigate and alleviate hunger in emergency times. Second is that state parties to the ICESCR are required to take steps to *progressively* achieve the right to adequate food, also known as the principle of progressive realization. The principle compels the state parties to move ‘as expeditiously as possible’ toward this goal. Article 2(1) of the ICESCR further asserts the state parties to:

...take steps, individually and through international assistance and co-operation, especially economic and technical, the maximum of its available resources, with a view to achieving progressively the full realisation of the rights recognised in the present Covenant by all appropriate means, including particularly the adoption of legislative measures.

By ratifying the ICESCR and other international treaties recognizing the right to food, states agree to be bound to three categories of state obligation: the obligation to respect, protect, and fulfil. The state obligation *to respect* requires states not to take any measures that would result in preventing individuals from having access to adequate food and to feed themselves. Indeed, the right to adequate food is primarily to be realized by right holders themselves through their economic and other activities. The state obligation *to protect* implies that states take measures to ensure that third parties (individuals, armed groups, enterprises, etc.) do not deprive individuals of access to adequate food. Under this

obligation, the state could be held liable for violations of the right to adequate food committed by non-state actors. The state obligation *to fulfil* demands proactive measures from the state to facilitate and provide access to food. For example, as a last resort, states must provide food whenever an individual or group is unable, for reasons beyond their control, to enjoy the right to adequate food by the means at their disposal.

Current Implementation of the Right to Food

At the international level, the implementation and the current development of the right to food mostly rely on the work done by the Committee on Economic, Social and Cultural Rights and the Human Rights Council, which was before 2006 known as the Commission on Human Rights.

The Committee on Economic, Social and Cultural Rights, established in 1985, is responsible, among others, to monitor the implementation of economic, social, and cultural rights by receiving and assessing state reports. All ratifying states are obliged to submit regular report on adopted measures and progresses made in achieving the observance of the ICESCR rights, every 5 years. The Committee examines each reports and addresses its concerns and recommendation in the form of concluding observation. The Human Rights Council has mandated several working groups and expert individuals, referred to as “Special Rapporteur on the Right to Food,” to investigate current challenges and further provide recommendations to meet such challenges. To meet the mandates, the Special Rapporteur usually conducts country visits and performs studies on specific topics, such as agroecology, land rights, seeds, nutrition, or value chains.

In several countries, the right to food is recognized in the national constitutions. According to a FAO right to food study in 2011, the right to food is recognized explicitly in the constitution of 23 countries. In addition, the right is recognized implicitly, for instance, by means of a broader right or by a directive principle, in the constitutions of 33 countries. Due to direct effect of international provisions, the right to food has effect in at least another 51 countries. Overall, the right to

food is thus legally applicable in 107 countries (Knuth and Vidar 2011).

The current status of development of economic, social, and cultural rights in the United Nations is the establishment of an optional protocol to the ICESCR in 2008. Once entered into force, this protocol will empower the Committee on Economic, Social and Cultural Rights to also receive individual communications and interstate communications. At the time of writing, the protocol has been ratified by five states, which are half of its ten-ratification requirement.

The international profile of the right to food allows its realization to move beyond the national borders (Kent 2005).

Between the Right to Food and Food Security

There are some similarities between the concept of the right to food and food security, noting that both emphasize a situation, at the individual level, pertaining to food availability, accessibility, safety, and cultural acceptability.

It is observed that states recognized the concept of the right to food in both international documents pertaining to the food security. In Paragraph 1 of the Rome Declaration 1996, states “reaffirm the right of everyone to have access to safe and nutritious food, consistent with the right to adequate food and the fundamental right of everyone to be free from hunger.” As such it was again reaffirmed in 2002, at the World Food Summit: Five Years Later, where states also agreed “to develop a set of guidelines to support Member States’ efforts to achieve the progressive realization of the right to adequate food in the context of national food security.”

Regardless of such a concerted and long endeavor at international level, the meaning of food security in connection to the right to food is ambiguous. In an attempt to clarify the connection between the two requires one to compare the distinctive attribute of their objectives and procedures. With regard to the objectives, the motivation for achieving food security can be based on a number of grounds, ranging from moral grounds

to more market-oriented motivations. Human rights, on the other hand, are exclusively based on the very idea of human dignity and autonomy which entails a priori values. Thus, from a human rights perspective, all other consideration would be secondary in nature. With regard to the subject of procedure, it looks at the nature of food security as part of international and/or national policy, rather than the legal concept as the right to food is (Alston and Tomasevski 1984). Such would imply recognizing the element of international treaty and customary international law of the right to food, with relatively clear and binding normative contents. Furthermore, the acknowledgement and internationally acceptance of the right to food, which are demonstrated by state ratifications, may conclude that as a human right, the right to food has a precise content. It can be violated and the violation can be the subject of judicial or quasi-judicial remedies (Mechlem 2004).

In conclusion, the concepts of food security and the right to food are closely linked to each other. It is in the procedural circumstances of the right to food that food security can be realized. Relying on the application of the doctrine of state obligation to respect, protect, and fulfil, one could expect a progressive realization of the right to food at the individual level. Furthermore, as the concepts of both food security and the right to food become more accepted and used interchangeably, realizing the right to food has been argued to include the application of the rights-based approach to food security (Barth-Eide 2005). This means applying good practices inspired by the human rights logic, namely, participation, accountability, nondiscrimination, transparency, and empowerment into food security programs and policies. However, the right to food does not claim to eradicate hunger or to achieve food security faster, or to reduce the importance of experiences gained from food security policies. Indeed, considering the closeness of both concepts and the considerably similar international acceptance thereof, attempts to realize the right to food need to be integrated with existing experiences with food security, with additional new dimensions that pose some arbitrary limits to them.

Contemporary Challenges on Food Security

Scholars and analysts have generally defined three situations of food insecurity: chronic or long-term food insecurity, seasonal, and transitory. The first refers to a situation where people are unable to meet their minimum food requirement for sustained amount of time. The second and the third imply a temporary food insecure situation as a result of sudden drop in the ability to produce or acquire food, which can result from natural disasters of harvest failures.

Natural disasters such as floods, droughts, earthquakes, and other weather-related phenomena can affect food security, destroying, for example, physical and economic capitals of food stocks and harvests. The effects are particularly adverse for the poor. This is primarily the result of three factors. Firstly, most low-income countries are located in regions that happen to be at far higher risk of natural hazards. Secondly, within countries the poor are normally affected much more than others due to economic and social factors, including race, class, gender, and ethnicity. The majority of the poor cannot afford living in locations with lower risks, they live in poorly built houses, and women and children are often hit the hardest, bearing the brunt of food and nutrition security impacts. Thirdly, there may already initial discriminating practices towards the poor regarding the allocation of the targeting compensation for natural hazards (de Haen and Hemrich 2007).

As the impact of such events to food security can be long-lasting, establishing measures to reduce natural disaster risk and build resilience is being advocated. The aim is to develop the ability of a system, community, or society to adapt to shocks in order to maintain an acceptable level of functioning. Crucial in such endeavor is to adopt measures that aim not only to eradicate the immediate catastrophic impacts but also to integrate those efforts into food security strategies as part of overall poverty reduction (Skoufias 2003).

Indeed, while food security can result from unfortunate events, as a social phenomenon, its root of causes is often structural, manifested in persistent status of vulnerability. This implies

investigating events as well as intrinsic characteristics of exposed groups of people to determine who will be affected and to what degree (Dilley and Boudreau 2001). Vulnerability approach emerged from the realization that the underlying vulnerability status of a population is a more important determinant of the extent and duration of a food security crisis, and thus relevant for adopting its solutions, than the discrete natural hazards or sudden drop of food stocks that may trigger food security (Prowse 2003).

In addition to vulnerability framework, the Household Livelihood Security (HHLS) framework grew out of a food security perspective but is based on the observation that food is not the only basic need. A livelihood “comprises the capabilities, assets (resources, claims, and access) and activities required for a means of living; a livelihood that is sustainable can cope with and recover from stress and shocks, maintain or enhance its capabilities and assets, and provide sustainable livelihood opportunities for the next generation” (Frankenberger 2003). Livelihood security, then, refers to adequate and sustainable access to income and resources to meet basic needs. This means to include a wide range of issues, such as land tenure, sustainable agriculture, potable water, health facilities, educational opportunities, involvement in policymaking, and time for community participation. Livelihoods include a range of on-farm and off-farm activities that together provide a variety of procurement strategies to make a living. Notably, the status of each individual and household’s livelihoods is based on the household’s endowments and its position in the legal, political, and social fabric of society (Baro and Deubel 2006).

Consequently, political and economic interventions on food security as well as humanitarian food aid may be not directly related to food itself. Power relations influencing the distribution of land, military insecurity, and political oppression impeding people to produce food are a case in point. Additionally, the increasing roles of private actors, as well as the relationship between state and market, is dominantly influencing the governance of food security policies at the national

level (Hospes and Hadiprayitno 2010). Pollution affecting the safety of food and food production are another case in point. Against this framework, the future of food security is closely connected to the complexity of law and practice that govern the arrangements of food production, distribution, consumption, and sustainability, as well as accountable economic growth policies and active preparedness measures.

Summary

Several major shifts in food security studies and policies have occurred since the 1970s. First, the unit of analysis has moved from the global/national level to the local/household/individual level. Second, the scope of analysis has shifted from a “food availability” approach to an emphasis on the performance and sustainability of household access to livelihoods. Third, subjective perceptions of food security among local populations now complement objectively measurable indicators of food security.

International organizations, national governments, and nongovernmental organizations who are responsible and assuming the tasks to carry out the food security programs and policies in the world hold a wide variety of opinions and have developed a wide variety of frameworks for tackling the issue of food security. These frameworks are congruous with specific scientific approaches to food security and act as frameworks for orienting policies.

The parallel between food security and the right to food is particularly relevant as the concept of “adequate” food has been further elaborated along and beyond the lines quoted above on food security. Both concepts argue that on the one hand the availability at all times is relevant and on the other hand adequacy is understood to mean sufficient to satisfy dietary needs, free from adverse substances, and acceptable in a given culture. While food security offers its flexibility and adaptability into different measurable indicators and policy measures, the right to food advances the concerted effort of eradicating hunger as legal obligation, to which some limits and

requirements apply to hold the duty-bearer, state accountable, and protect the entitlements of right-holder, the individual.

Current challenges pertaining to climate change; natural disaster; pollution; corruption; decreasing availability of land, water, and other resources; as well as the impact of food security to nutrition and health status particularly to vulnerable groups are analyzed and addressed using different approaches. Frameworks on vulnerability and household livelihood security are only few that have been advocated to provide solutions as well as to understand the complexity of persistent problem of food security.

Food Security and Intergenerational Justice

Chaitanya Motupalli
Graduate Theological Union, Berkeley,
California, USA

Introduction

In today's Western world, when we can order food at our fingertips, choose from a wide variety of everything, and have fruits and vegetables in and out of season, it is disheartening to know that every night millions of people are going to bed hungry. It was estimated that there were 780 million undernourished people in 2014–2016 (FAO et al. 2015, p. 9). Certainly, this number has come down from over a billion in the early 1990s, but still there is a lot of work that needs to be done to make the world food secure.

While achieving food security for the 780 million undernourished people is a challenge in and of itself, the task is even more daunting if we consider making future generations food secure as well. World Economic Forum estimates that by 2050, a global population of 9.8 billion will demand 70% more food than is consumed today (WEF, n.d.). There will be an additional stress on the food and agricultural sector worldwide. It is also likely that future generations will be exposed to an even greater state of food insecurity, than the most impoverished people of our times. In that light, it is essential to consider the questions of food security for future generations. This essay is an attempt in that regard. As far as the direction of

the essay is concerned, we will first discuss what entails food security. Then, we will consider the future of food security in the context of climate change. Upon establishing the fact that future generations are vulnerable to food insecurity, we will delineate an ethical framework for intergenerational justice for food security.

What is Food Security?

The contemporary narrative of food security started taking shape in the 1940s, in the aftermath of World War II. And as for the concept of food security itself, it was formally recognized at the 1974 World Food Summit (Pritchard 2016, pp. 2–3). Since then, there have been many renditions of what defines food security. In 1996, it was observed that there were as many as 200 definitions in circulation (Smith et al. 1992). To understand food security comprehensively, we need to understand the concept in all its dimensions. We shall attend to that task in this section.

The most widely referred to and accepted definition of food security comes from the 1996 World Food Summit. The roots of this definition lie in Resolution 1/64 of the *Universal Declaration on the Eradication of Hunger and Malnutrition* at the 1974 World Food Conference. In the resolution, the council reaffirmed:

the urgent need for effective international action aimed at ensuring the availability at all times of adequate world supplies of basic foodstuffs, so as to avoid acute food shortages in the event of widespread crop failure, natural or other disasters, to sustain a steady expansion of consumption in countries with low levels of per caput intake, and offset fluctuations in production and prices (FAO 1974).

Although the resolution is not a definition as such, it outlines the concept of food security. Food security here is conceived in terms of food supply and price stability of basic foodstuffs at the national and international level. Therefore, in the years following the 1974 conference, the focus of efforts by various national and international organizations was on increasing food production and implementing appropriate national food stocks policies in developing countries. That strategy, however, was reconsidered after the publication

of *Poverty and Famines* by the economist Amartya Sen (1981). In his work, Sen dismantles the notion that food insecurity was due to the lack of availability of foodstuffs. Instead, he suggests that food insecurity is due to the lack of an individual's ability to "establish entitlement of enough food" (Sen 1981, p. 8), that is, her ability to access food. As a result of Sen's work, the aspect of "access to food" at the individual and household level was added to the concept of food security. This insight is evident in the FAO 1983 definition:

Ensuring that all people at all times have both physical and economic access to the basic food that they need (FAO 2006).

In addition to the recognition from Sen's insight of the importance of access to food, food security was also recognized to be intricately connected to the social and political arrangements of people as those arrangements dictate access to food (Pritchard 2016, p. 3). Efforts then were geared toward improving the sociopolitical and economic arrangements of people, while still attending to agricultural production. It was affirmed in the late 1980s that the development of agricultural production is contingent upon the convergence of financial, economic, and social policies implemented by each country (Shaw 2007, p. 200).

Despite all the concerted efforts until the 1990s, however, the incidence of malnutrition continued to worsen, and there were still 800 million chronically undernourished people in the world. Consequently, the FAO worked alongside the World Health Organization (WHO) to identify the causes, nature, and magnitude of the problem, and to come up with a strategy to address it. They discovered that not everyone was getting the full benefits of food consumption. The result was the recognition that there is a need to improve the ways in which food is allocated within a household and the conditions that facilitate the nutritional well-being of all people. The "desirable intakes of macronutrients and micronutrients, combined with adequate health and care, as well as availability of safe water" (FAO and WHO 1992, p. 3) were considered crucial for food security.

Taking into consideration of these various developments, the 1996 definition was formulated:

Food security exists when all people, at all times, have physical and economic access to sufficient, safe and nutritious food that meets their dietary needs and food preferences for an active and healthy life (FAO 1996).

Incorporating the changes in the official policy thinking and scholarship on various aspects of development and hunger, as human geographer Bill Pritchard (2016) notes, this definition philosophically grounds the concept of food security in three significant ways. Firstly, it frames food security in people-centric terms: food security is achieved when people's food needs are met, and not necessarily when there is an adequate supply of food or when they have access to it. Secondly, it is aspirational in orientation: the phrase "all people, at all times," speaks of the aspirational goal. The fact that we were unable to reduce the number of undernourished people to half by 2015, as was the World Food Summit 1996 target, helps us understand how hard it is to realize the goal of having "all people, at all times" have physical and economic access to adequate nutritious food. Finally, the inclusion of the terms "nutritious," "safe," "food preferences," and "active and healthy life" underscores the importance of the social worlds of people and their health in the pursuit of food security (p. 2).

This definition encompasses four dimensions, or pillars:

Food availability: The availability of sufficient quantities of food of appropriate quality, supplied through domestic production or imports (including food aid).

Food access: Access by individuals to adequate resources (entitlements) for acquiring appropriate foods for a nutritious diet. Entitlements are defined as the set of all commodity bundles over which a person can establish command given the legal, political, economic, and social arrangements of the community in which they live (including traditional rights such as access to common resources).

Utilization: Utilization of food through adequate diet, clean water, sanitation, and health care to

reach a state of nutritional well-being where all physiological needs are met. This brings out the importance of nonfood inputs in food security.

Stability: To be food secure, a population, household or individual must have access to adequate food at all times. They should not risk losing access to food as a consequence of sudden shocks (e.g., an economic or climatic crisis) or cyclical events (e.g., seasonal food insecurity). The concept of stability can therefore refer to both the availability and access dimensions of food security (FAO 2006).

As can be understood, the concept of food security is complex and interconnected with various other factors. Longtime associate of the United Nations' World Food Program, D. John Shaw, presents the multidimensionality of food security well. He graphically represents food security as the core of three concentric circles. The innermost circle includes a network of food and nutrition security concerns like safe water and sanitation, childcare, health and disease control, etc. These are location specific and the importance of the concerns varies from location to location. However, they all impact food and nutrition security just like the concerns at the regional and national level, which make up the circle in the middle. The concerns in the middle circle include basic services like health and education, technology, food and other subsidies, assets and human rights, including land rights. These concerns impact how the local concerns are played out. The outer circle encompasses the global concerns, such as environmentally sustainable development, population growth, water resources, human security and rights, climate change and the current patterns of globalization, women and gender concerns, and issues of immigration and poverty. These global concerns affect the local and regional concerns in the two inner circles (Shaw 2007, p. 384). On the whole, various and multidimensional concerns directly or indirectly impact food and nutrition security. With this basic understanding of food security, we may now consider the future of food security.

Food Security and the Future

Although there are many factors that influence food security, the prominent ones at the global level are the advances in seed and agricultural technology, climate change, and the socioeconomic and political arrangements (Shaw 2007, p. 437). In this section, we will discuss how climate change specifically impacts food security in the future. The main purpose of this discussion is to establish the fact that food security of future generations is indeed impacted by climate change, which is one of the biggest challenges of our times.

In nonscientific terms, environmentalist Bill McKibben (2011) succinctly explains well the relationship between climate change and food security: it is getting too hot for crops to grow. The warming of the earth's atmosphere will continue to impact the productivity of crops. To put it in perspective, by the end of the century an average July day will almost be hotter than the hottest heat waves we experience now, and in such a context, some of the crops will not be able to grow (p. 154). Even the quality of food is impacted because of the increasing temperature and decreasing crop growth period (Kang et al. 2009, p. 1671)

In addition to temperature, the availability of water and nutrients, concentration of CO₂, and the interaction of crops with other plant pathogen also impact the ability of crops to produce. In fact, these impacts from various factors make agricultural systems much more complex and hard to conclusively predict how they will be influenced by climate. Yet, in an effort for us to fully understand the gravity of the impacts of climate change, the Intergovernmental Panel on Climate Change (IPCC) attempts to predict the effects of climate change on agricultural systems.

The impacts of climate change on crops vary across crops and regions and adaptation scenarios. At the global level, the production potential is projected to increase with the increasing temperatures over a range of 1–3 °C, but above this range the potential is expected to decrease (IPCC 2007, p. 298). For the period of 2030–2049, it is

estimated that 10% of the projections show 10% increase in yield, as compared to the late twentieth century. Also, 10% of the projections show a loss of more than 25%. After 2050, depending on the level of warming, the risk of severe impacts on crop yield increases even more (IPCC 2014, pp. 17–18).

Furthermore, the impact of climate change on water resources also influences agriculture. Future climate change is characterized by unpredictable weather conditions and prolonged periods of floods and droughts, which directly impact the crop yields by damaging the crops at certain developmental stages. For instance, floods result in soil erosion, which contributes to substantial agricultural loss. There is also a possibility of climate change affecting the aspect of food utilization. Populations in water-scarce regions are likely to face decreased water availability, particularly in the subtropics, with implications for food processing and consumption (IPCC 2014, p. 18).

The FAO (2016) estimates that most regions of the world are projected to see a decline in the number of people at risk of hunger by 2050 because of continuing economic progress. But when climate change is added to the mix, the numbers change drastically: “With climate change. . .the population living in poverty could increase by between 35 and 122 million by 2030 relative to a future without climate change, largely due to its negative impacts on incomes in the agricultural sector” (p. xi-xii). And, sadly, since majority of the population in the developing countries derive their livelihood from agriculture, without any doubt, those populations will be rendered most vulnerable to various risks, including food insecurity. Of all the different groups of people that will be impacted by climate change, future generations in the developing countries will be affected the worst. Now the question that needs to be addressed is, how do we meet the challenge of food security for future generations in the light of impending climate uncertainty? An equally important question to consider first is this: What is the ethical framework that needs to guide our policies and thinking? The following section attempts to answer the latter question.

Food Security and Intergenerational Justice: An Ethical Framework

One of the ways in which food security of future generations may be protected is by upholding the right to food, which was recognized as a fundamental component of a sustainable solution to the world food insecurity. It is a sustainable solution because, for the realization of the right to adequate food, countries are expected to promote good governance for sustained economic growth, sustainable development, and work toward the eradication of poverty and hunger. In that sense, not only does the right to food give voice to a wide array of people, including future generations, but it also provides a coherent framework to address critical governance dimensions of the fight against hunger.

Although the right to food doesn't determine the priority and degree of hunger or the need of the people who are most vulnerable, it sets a standard that nations might want to meet. Resorting to the *rights* framework in the context of eliminating world hunger has an added advantage: it allows the problem to be addressed from a political front. After all, as philosopher Rüdiger Bittner (2001) argues, world hunger is a political problem (p. 26). In any political community where the members have something to say about their government, some such principles have to be worked out which sustain and enhance a common culture and ethos of that community. Right to food is one such principle that testifies to the character of the human community at large.

More importantly, the right to food carries with it some significant obligations. Since right to food could also be considered a social issue, human rights activist Xiaorong Li (1996) argues, the society at large, not individuals, is responsible for protecting it. Also, for the right to be effective, it requires support from institutions that foster a stable political and economic order. In fact, such an order is a prerequisite to prevent deprivation and to protect each person's opportunity for access to adequate food. In addition, it places the responsibility on governments to guarantee access to adequate food for people. If governments fail to take responsibility, then international institutions that recognize the universal right to food have a

duty to exert needed political pressure for action. Furthermore, in case of crisis situations, such as starvation, the international community through international institutions has a humanitarian duty to respond and save lives.

At this point, we need to remember that discussions on intergenerational justice often end up in a stalemate when posed as matters of rights. For various philosophical and practical reasons, some scholars cannot agree that future people can have rights. Philosophers Joel Feinberg and Wilfred Beckerman are good examples in this regard. Despite the disagreement on the aspect of rights for future generations, there is a consensus that future generations do have interests.

Political theorist Fabian Schuppert (2011) suggests that our moral concern for future generations can be justified by appealing to the basic moral assumption that "all persons share a set of fundamental interests and that the fundamental interests of future people weigh just as heavily as the fundamental interests of present people..." (p. 304). For Schuppert, a person's fundamental interests are "a set of liberties, goods and things that give her equal opportunity to flourish" (p. 316). Included in the fundamental interests are the basic needs of people, such as food, water, shelter; needs pertaining to the physical environment in which one lives, e.g., a healthy environment with functioning eco-systems; and the needs pertaining to one's social environments, like economic and political liberties. So, even if there is hesitancy in applying the right to food framework for future generations, it still must be defended because it safeguards their fundamental interests.

When 780 million people are still suffering from undernourishment in the present times, it is valid to question how one can think of food security for the future. A caveat before responding to that question: when we are considering the food security of future generations, we are not setting up the food needs of the most vulnerable people of our times against those of the future generations. Instead, we are thinking of ways in which we can address the concerns of food security of the present generations as well as those of the future simultaneously.

To answer the question, the three principles of intergenerational ecological equity that

legal scholar Edith Brown Weiss (1992) proposes may be invoked. In a summary fashion, intergenerational equity is achieved through comparable options, comparable quality, and comparable access. The first principle is that each generation must conserve options. Options are opportunities that will allow future generations to solve the problems they might face, and satisfy their values. Those options are available in and through the diversity of natural and cultural resource bases. So, the diversity of these resources needs to be conserved, as future generations are entitled to options available to them comparable to that which the previous generations have enjoyed. In terms of food security for future generations, the principle of options may pertain to conserving institutions of good governance, availability of food, seed and agricultural technologies, and the food preferences of people.

Secondly, the principle of comparable quality: “[e]ach generation should be required to maintain the quality of the planet so that it is passed on in a condition no worse than that in which it was received” (p. 22). This principle recognizes that future generations are entitled to a certain quality of the earth, just like their forebears. This principle translates into conserving the quality of soil and environmental conditions, so that the quality of the crops may be conserved for future generations.

Finally, the principle of comparable access states that “each generation should provide its members with equitable rights of access to the legacy of past generations and conserve this access for future generations” (p. 23). This principle highlights the conservation of non-discriminatory access to the earth and its resources. This is an important consideration because even though we maintain comparable options and comparable quality, it is futile unless the future generations have comparable access. The aspect of access to food for food security should cut across the generational divide based on this principle.

While Brown Weiss’ principles of intergenerational justice have many attractive features and they stipulate the minimum requirements of intergenerational justice, they do not set boundaries of the purview of justice between generations. In other words, how far can we go to fulfill

the demands of justice for future generations? For that, the principles of international intergenerational justice that philosopher Janna Thompson (2009) proposes are critical:

The first, and primary, principle is that polities, and other international agents, ought not to violate each other’s entitlements, or the entitlement of communities within each other’s borders, to maintain intergenerational relationships, practices and institutions which satisfy basic requirements of justice and to fulfill their intergenerational responsibilities within the framework of these relationships and institutions. . . .

The second principle is a requirement of remedial justice. Polities and other international agents ought to make reparation for violations of the requirements of the first principle with the objective of bringing about a state of affairs in which both perpetrators and victims (or their successors) are no longer justified in regarding the violation as standing in the way of establishing or re-establishing just relationships (p. 163).

The first principle maybe referred to as the principle of nonviolation. As much as there is a need for polities and international agents to fulfill their intergenerational responsibilities, they cannot violate each other’s entitlements or the entitlements of communities within each other’s borders. To put it differently, even though there is a need to uphold the right to food to foster food security for future generations, polities as international communities or international agents cannot violate the entitlements of communities within anyone’s borders in the present. Applied generationally, this principle serves the purpose of safeguarding the entitlements of the present generations from being sacrificed for the sake of future generations. Yet, that doesn’t mean that the present generations do not have intergenerational responsibilities. It only means that there are limits for how far polities and international agents can go to fulfill their intergenerational obligations.

The second principle may be referred to as the principle of remedial justice. This principle recognizes the need for reparative justice so that just relations may be established within a national or international setting. Similarly, this principle may be applied to establish just relationships intra-generationally or inter-generationally. Consider, for instance, an international institution S, in an

attempt to make the future generations food secure, jeopardized the ability of people at a particular time period in a country B to access a certain staple food. In such a case, the principle of remedial justice requires that S make reparations to the communities of B in the present day. At any given point of time, this principle, thus, helps in rectifying the wrongs that might have happened before that point of time.

Conclusion

In this essay, we have discussed the basics of food security and the possible future of food security in the context of climate change. Given the vulnerable position of future generations to various risks, including food insecurity, we have considered five intergenerational principles that could be used to think through the manner in which we can strive for food security for future generations. While the principles of comparable options, comparable quality, and comparable access help in thinking about the demands of intergenerational justice without compromising the demands of current generations, the principles of nonviolation and of remedial justice set the boundaries of intergenerational justice. The two latter principles also help in considering intergenerational justice within the framework of the international geopolitics. In sum, whether it is the 780 million undernourished people of our times or future generations that will be vulnerable to food insecurity, the current generations have a moral obligation to respond to the basic food needs of all people, at all times. Given that the current generations are equipped with the needed technology, adequate supplies of food, and international support to make the world food secure, if nothing is done in that regard for future generations, they may charge us with recklessness and apathy.

Famine; Food insecurity; Hunger; Malnutrition; Starvation

Introduction

International trade has the potential to significantly affect food security outcomes. Changing production and consumption patterns that result from increased international trade flows affect income levels and income distribution, which are the fundamental determinants of food security. The debate over the role of international trade in food security is often framed as a debate over the ethics of international trade; such a framework misdirects the debate onto an unproductive path.

There is (almost) universal agreement on the objective of universal food security, and there is very little gray area in the ethics surrounding this objective. The debate about international trade's role in achieving food security is more productively framed as a debate over the effects of international trade on food security. These effects are complex and difficult to identify, however, and most studies do not provide conclusive results.

Measuring Food Security

Food security is an evolving concept. The most commonly cited definition is from the Food and Agricultural Organization's (FAO) (2001) State of Food Insecurity, which describes food security as existing "when all people, at all times, have physical, social and economic access to sufficient, safe and nutritious food which meets their dietary needs and food preferences for an active and healthy life." This is a broad definition that captures many important innovations in measuring and defining food security. The evolving understanding of food security has resulted in new ways to measure food security and generated new perspectives on the effects of trade and policy strategies to address food security. Three important structural changes in the understanding of food security are described here.

The first important change is a movement from food security indicators based on food supply to indicators based on peoples' access to food. Food security was historically assessed at the national level by comparing a country's estimated supply of food (measured by aggregating domestic production, imports, carry-over stocks, and food aid) per capita to an approximation of an individual's minimum caloric requirements (e.g., the average number of calories required for a moderate level of daily activity). If available caloric supply per capita was greater than or equal to this estimated level of need, then a country could be said to be food secure.

The fundamental drawback of food security measures based on national supply is that they abstract from issues of intranational distribution. Most developing countries are characterized by

wide income inequality, and periods of high food prices can reduce access for low-income people in a country that would be viewed as having sufficient quantities of food per capita, if measured at an aggregate level.

Sen (1981) formalized the concept of access or “entitlements” to food and showed that measures of food supply at the national, or even regional, level are not sufficient indicators of food security. Individuals’ access to sufficient quantities of food determines their food security status. This access was first understood to mean sufficient income to purchase food at prevailing prices, but has since taken on a broader interpretation to include social access (e.g., intra-household distribution) and access to safe and nutritious food.

The units of analysis in food security studies have narrowed to better measure food access in recognition of the entitlement concept. Household surveys have become important tools in assessing food security at a more micro level than national supply data would allow. Surveys are evolving over time to include components of intra-household distribution, which provide researchers and policymakers with information on allocation of food between male, female, and child members of a household.

A second important structural change has been the use of anthropomorphic measures, such as stunting and low weight, in assessing food security status. These measures provide information about outputs of food security (i.e., current status) instead of just inputs into food security (i.e., food supplies and purchasing power). Anthropomorphic measures can provide accurate snapshots of the current state of food security, but are necessarily backward looking and do not consider the potential for future entitlement failures or subjective feelings of future food access.

A third major change in the analysis of food security has been an increased emphasis on micronutrient deficiencies. Traditional measures of food security that were based on available calories neglected the importance of micronutrients and could have overlooked “hidden hunger” (IFPRI 2010). Deficiencies of important nutrients such as iodine, iron, vitamin A, and zinc have serious short-term health consequences and can generate

long-term developmental delays and deficits. These include anemia, susceptibility to infections, and blindness in the short run and reduced cognitive capacity in the long run.

Despite significantly different approaches (see Masset (2011) for a discussion of some methodological issues), most international measures of food security report progress in reducing the prevalence and severity of global food insecurity. The FAO’s (2011) *State of Food Insecurity in the World* reports decreasing rates of undernourishment in all aggregated geographic regions, though not all countries, since 1990. Global undernourishment is estimated to have decreased by 19% since 1990. Likewise, IFPRI’s *Global Hunger Index* (2011) reports lower hunger scores in all regions (but not all countries) than in 1990. Several Asian countries have made enormous progress in improving food security, led by large changes in China and South East Asia. Latin American and Caribbean countries have also made significant progress, led by sharp declines in hunger in Brazil. African progress has been mixed, with worsening situations in the Democratic Republic of Congo and the Ivory Coast.

The Links Between Food Security and International Trade

Discussion about attaining food security at a national level is often framed as ethical debates over domestic food self-sufficiency versus openness to international trade. Ideology often overtakes such debates, but if the ethical objective is to improve food security outcomes, then it is more useful to center the debate on international trade’s effects on food security. The effects are complex and there are several confounding factors that can cloud the identification of causal relationships. The important avenues through which international trade can affect food security are discussed below.

Specialization and Income Growth

One of the core tenets of economic theory is that countries that are free to trade with each other will specialize in the production of products in which

they have comparative advantages. Specialization will increase production and generate higher total income in both countries. Higher income, when viewed through the lens of Sen's entitlements, should result in better economic access to food and improved food security. This argument extends to countries that adjust their production patterns away from food; higher income that is generated by more efficiently producing and exporting nonfood products can be used to import more food than was available prior to undertaking international trade. Lower domestic food production need not reduce food security – the linkages run from specialization to income growth to poverty reduction to improved food security.

Specialization involves reallocating resources and necessarily increases demand for some inputs and reduces demand for others. Such reallocation changes relative factor payments (wages to laborers, rent to land and capital owners) and generates winners and losers in the short run. A large portion of poor, food-insecure households derive the majority of their income from wage labor, so the direction of real wage movements after liberalization will have important effects on food security. As a country specializes in production of products that are labor-intensive, demand for laborers will increase and there will be upward pressure on wages. Such specialization could, however, reduce demand for land, thereby reducing rental rates and income to landowners. It is impossible to generalize the effect of liberalization on wages across countries, as each country's experience will depend on the directions of specialization.

Terms of Trade and Food Prices

The relative prices of imports to exports will change as countries remove, or reduce, trade-distorting policies. Again, it is impossible to generalize the direction of food prices across countries because of the complicated nature of distortionary policies that are commonly found in agricultural industries and the incomplete nature of trade agreements. For example, consider a liberalizing agreement to reduce import barriers between trading partners. As import barriers are reduced in large importing countries, demand for imported food will increase, thereby increasing

the world price of food; this is expected to increase income and improve food security for net food producers and worsen food security for net food consumers. The effects of broad-based multilateral trade agreements (in the tradition of World Trade Organization agreements) on food prices are much more difficult to identify. The World Trade Organization's (WTO) Uruguay Round agreements (which include the Uruguay Round Agreement on Agriculture) and the Doha Development Agenda (DDA) proposals include disciplines on a wide range of trade-distorting policies. Lower import barriers in large countries are expected to exert upward pressure on world food prices, but these effects would be dampened by lower levels of domestic support in developed countries. Disciplines on other trade-distorting policies, such as food safety regulations and export competition, further complicate the analysis. The net effects of a new round of trade liberalization on food prices would depend on the breadth (coverage of a range of policies) and depth (size of cuts to distortionary policies) of new rules. Computable general equilibrium models that incorporate DDA proposals generally predict increased prices for staple food commodities (see discussion, below).

Foreign Direct Investment

International integration can also involve closer investment ties between trading partners, which manifests as foreign direct investment (FDI). More than 2700 bilateral investment treaties have been signed (UNCTAD 2010) and many preferential integration agreements extend beyond trade in goods to include rules on FDI. The primary avenue through which FDI can improve food security in developing countries is income growth as a result of technology transfer from developed countries. Foreign direct investment brings modern technology and production methods to relatively inefficient industries in developing countries and can increase productivity, and therefore income, in host nations. The ownership of the proceeds from increased productivity is an important factor in determining the benefits of FDI, however. It can be difficult to find a balance in which the innovating foreign

firm receives sufficient returns to justify the FDI and workers in the host country receive a portion of the fruits of higher productivity. See Saggi (2002) for a survey of FDI and technology transfer.

The acquisition of agricultural land by foreign firms and state governments has received a great deal of attention in media sources (von Braun and Meinzen-Dick 2009) and led to public pressure to block some proposed projects. State actors, including China, South Korea, and several Middle East states, have been motivated to acquire foreign agricultural land in attempts to stabilize future food supplies. Though such projects have the potential to improve productivity in low-productivity host nations, this form of FDI has been controversial because of concerns about foreign investors' commitments to control environmental impacts and concerns about the insecurity of land tenure in many developing countries. Such land is often formally owned by the state, and inhabitants who use the land without formal title may be forced to relocate.

Stability

Shocks to agricultural production are inherently covariate across producers – weather, pest, or violence shocks that affect one producer are likely to affect all producers in the surrounding area. The covariate nature of shocks makes production of food in any one geographic area unstable and a population that relies only on regional production is vulnerable to production failures that could significantly affect market supply and prices. Reliance on regionally produced food is one end of the trading spectrum, with global free trade marking the other end. A population that acquires food supplies from a global market without trade barriers is necessarily less vulnerable to production-induced supply and price volatility, because a larger market diversifies the production risks that affect agriculture. A globally integrated food market would transmit price signals from locations with shortages to locations with surpluses and trigger arbitrage-induced movements of commodities.

The food crisis of 2008 laid bare one of the important downside risks that developing countries

face by increasing their dependence on foreign food supplies. Several governments in net food exporting developing countries imposed export restrictions on food in attempts to constrain domestic food price inflation. Such policies are necessarily beggar-thy-neighbor because lower world supply applies upward pressure on world prices and negatively impacts net food-importing countries. Net food-importing developing countries that had historically relied on these products were forced to either pay higher prices or find alternative sources. This raises a clear ethical question for governments that impose export restrictions, but such decisions are political and it may be unrealistic to expect that concerns about negative effects on trading partners will trump domestic political pressure in times of high food prices.

World Trade Organization disciplines on export restrictions did not apply to the types of policies that were implemented over the past few years (Headey 2010), and such anti-trade behavior remains unchecked. Trust in the global food trading system has been shaken by these policies and there have been movements in several countries to reduce reliance on imported food. It is important to note that restricting exports (anti-trade policies) form the core of the problem, not the opening of importing countries to food trade (pro-trade policies).

Economic theory, and some empirical evidence, suggests that free trade will increase income growth, reduce poverty, and stabilize food availability and prices. It is important to note, however, that these predictions are made in the theoretical vacuum of a first-best world in which there are no deviations from best policies. If one or more of the foundational assumptions of these models is violated, then accurate predictions about, for example, lower import barriers improving food security cannot be made. This is the basis of Lipsey and Lancaster's (1956) theory of the second best, which is crucial to understanding the effects of international trade agreements. WTO agreements allow implementation periods over which countries can adjust policies to adhere to their obligations, and not all industries are not liberalized to the same degree (e.g., trade-distorting policies in agricultural industries were not subject to many disciplines prior to the 1995

Uruguay Round Agreement on Agriculture). Such complications make it very difficult to project, even at a theoretical level, what will happen to income and food security in the short term as trade is liberalized. The case of export restrictions is a clear example of this – net food-importing countries that lowered food import barriers in anticipation of lower and more stable prices were met with new anti-trade export restrictions in exporting countries. This sequence of events may have worsened food security in some importing countries in the short run.

International Agreements

The trade rules that are most relevant to food security in developing countries can be found in the agreements of the WTO. The WTO is an international organization that oversees a range of trade-related agreements between 157 member countries, several of which are developing countries in which food insecurity is prevalent. The primary motivation for countries to pursue multi-lateral trade agreements under the WTO is to provide a stable and predictable rules-based international trading environment in which countries can specialize and reap the gains from trade. Most WTO agreements have been designed to reduce the prevalence of trade-distorting policies (i.e., policies that change producer and consumer behavior in a way that affects trade flows) in member countries. The WTO does not have a development, or food security, mandate (like international organizations such as the International Fund for Agricultural Development or IFPRI), but the policy reforms required of its member countries can have significant effects on income and welfare. The principle on which WTO negotiations rests is that freer trade will induce specialization, which will in turn increase incomes and improve food security outcomes.

The Uruguay Round Agreement on Agriculture (URAA), entered into force in 1995, is the WTO agreement that is most directly linked to issues of food security. The URAA spells out member countries' obligations with respect to food trade and domestic agricultural support

policies, and its disciplines are categorized into three pillars. Market access rules outline the maximum tariff rates that member countries agree to place on other members' imported products. Such rules could positively affect food security in two ways: first by increasing income in developing countries' export industries (through lower tariff barriers into developed countries) and second by decreasing the price of food imports into developing countries (through lower tariff barriers into developing countries). Producers in developing countries will, however, face more competition from international producers as import barriers fall.

The second pillar contains disciplines on domestic support measures that governments provide to agricultural producers. Domestic support is typically very low (and sometimes negative, through taxation policies) in developing countries, and these disciplines are most relevant to developed member countries. Lower domestic support in developed countries can reduce production levels, thereby increasing world prices; this can have offsetting effects on food security by increasing world food prices and by making exports from developing countries more competitive on the world market. The third pillar concerns export competition and contains rules on subsidies and export credit guarantees. It is most relevant for developed-country policies – the European Union accounts for almost all of global agricultural export subsidies. Export subsidies are used by exporting countries to unload domestically produced surplus commodities that are uncompetitive at world prices. A reduction in such subsidies could increase the prices for such products in importing developing countries but also render production from developing countries, from where exports are not subsidized, more competitive in global markets.

World Trade Organization member countries recognized that trade policy reforms could have negative short-term effects on food security in some net food-importing developing countries. This led to the Marrakech Decision (WTO [undated](#)) that acknowledged this possibility and has framed DDA round of trade negotiations. The proposals that have emerged from DDA

negotiations target deeper and wider cuts in agricultural tariff barriers and domestic support measures and include binding disciplines on food aid shipments. International food aid is widely viewed to have been used as a tool of surplus disposal by some donor countries, and competing exporters are seeking to limit the circumstances in which food aid shipments would be allowed. New rules on food aid will be difficult to enforce and are becoming less relevant as most donors have transitioned away from using food aid as a vent for disposing of surplus commodities (Cardwell 2008).

Several developing-country WTO members believe that they were not provided the market access to developed-country markets that was promised in UR negotiations because of “dirty tariffication” (in which tariff rates are inflated so that mandated tariff rate cuts do not result in improved market access) by developed countries. This practice did not violate member countries’ obligations, but was outside the spirit of the WTO’s liberalizing agenda and has been viewed as unethical by some commentators. Developing countries have responded by taking firmer bargaining positions in DDA negotiations, which has contributed to the glacial pace of progress. One result of developing countries’ stance is that they are likely to continue to receive “special and differential” treatment in future WTO agreements, in which they are granted extended implementation periods and special provisions for least-developed countries.

Other agreements in the WTO can also significantly affect food security. Disciplines on non-agricultural market access (NAMA) have the potential to impact trade flows more significantly than agricultural rules because the value of global nonagricultural trade far exceeds the value of agricultural trade. Access to developed countries’ services and manufacturing markets can have important income effects in developing countries with burgeoning nonagricultural sectors. Note, however, that trade barriers in nonagricultural industries are much lower, on average, than for agricultural industries. The effects of future NAMA policy changes will likely be smaller than the effects of changes to trade-distorting

agricultural policies because there are fewer reforms to be made.

There has been a proliferation of preferential trade agreements (PTAs) – sometimes referred to as regional trade agreements – in recent years, in which two or more countries agree to preferential trade barriers. There are currently more than 240 such agreements in force, and many involve blocs of developing countries. The effects of PTAs on food security vary, depending on the breadth and depth of their coverage. Some PTAs provide deep integration across countries by eliminating most trade barriers (e.g., the Southern Common Market, MERCOSUR), while others are narrow in scope and do not liberalize trade across a wide range of industries (e.g., the Southern African Development Community, SADC). The effects on food security will be proportional to the level of integration with trading partners. There are two important differences between PTAs and multilateral agreements that differentiate their effects on food security. First, most PTAs do not contain provisions for reduced domestic support to agricultural industries. This means that distortionary subsidies that induce overproduction in some countries may not be affected by PTAs. Second, some of the largest effects of multilateral trade agreements are expected to arise from improved access to developed-country markets. Preferential trade agreements that are struck between developing countries will not provide such access.

Evidence on Food Security and International Trade

The path of causal links from international trade to food security is long and complicated. There are several intermediate and confounding factors that have to go right for increased trade to improve food security outcomes. The nature of economics as a social science makes the identification of these effects difficult. Economic analyses of international trade policies cannot be conducted within the framework of repeatable randomized controlled trials that cleanly identify cause (change in trade policy) and effect (change in food security

status). Instead, economists rely on observational data to infer causal links through statistical studies. These studies leave much to be desired in the identification of the effects of international trade on food security. Three approaches to identifying the links have been summarized.

Case studies that describe individual countries', or regions', food security status before and after trade liberalization can be instructive about selective experiences but are problematic from an analytical perspective. Case studies are not internally valid, meaning that they do not control for the range of confounding factors that could impact food security outside the effects of trade changes. Nor are case studies externally valid; any conclusions drawn from such studies are relevant only to the case being studied. The very specific conditions of the market in which the study was conducted would not generalize across countries with different policies in different time periods. Policy prescriptions that are based on such analyses are viewed with caution because of these limitations.

Simulation models use economic theory and statistically estimated parameters to evaluate the expected effects of trade liberalization scenarios *ex ante*. These analyses better control for confounding factors by using parameters that have been estimated in statistical models. Simulation models typically take one of two forms (Abler 2006). Partial-equilibrium models simulate market behavior in disaggregated sectors to estimate the welfare effects of trade liberalization. Partial-equilibrium models are useful because trade liberalization occurs across industries that are very different, and such disaggregation allows for the modeling of industry-specific peculiarities. The primary drawback of partial-equilibrium models is that they do not allow for interindustry connections, which can be very important in the links from trade to income growth to food security.

Computable general equilibrium models also use econometrically estimated parameters to analyze trade liberalization scenarios *ex ante* but do so in a framework that aggregates across commodity groups and includes several, or all, sectors of the economy. These models include interindustry connections and can generate

estimated income effects, from which poverty and food security estimates can be derived. Computable general equilibrium models are the most commonly used tools for estimating the effects of international trade agreements, and several organizations manage large-scale models of this kind (e.g., GTAP at Purdue University and the MIRAGE model at IFPRI).

Anderson et al. (2006) use the World Bank's LINKAGE model to show that trade liberalization, as outlined in the DDA negotiations, would reduce poverty, particularly in developing countries. They do not explicitly estimate food security status, but the estimated reductions in poverty can be extrapolated to generate positive effects on food security. Hertel and Winters (2006) provide an overview of GTAP-based studies that estimate the effects of a DDA agreement on poverty. They find mixed short-term effects (increased poverty in some countries, decreased in others) and reduced poverty in the long run. Note that a link from poverty reduction to food security (through entitlements) must be made for one to draw conclusions about food security from such studies.

A third approach is to analyze the effects of trade liberalization *ex post* by econometrically modeling a measure of poverty or food security as a function of the implementation of international trade agreements. One such study (Bezuneh and Yiheyis 2009) finds that food availability decreased in the short run after trade agreements, but long-term effects are uncertain. The findings of such studies must be viewed with caution, however, because of the difficulty in identifying the effects of trade agreements on food security. There are important methodological problems in identifying cause and effect in econometric models of this type. Also, Bezunah and Yiheyis (2009) use national food availability (production plus imports plus food aid) as a dependent variable; food supply is not an accurate representation of food security.

Summary

The ethics of food security are clear; the pursuit of universal food security is almost unanimously

viewed as valuable. The role of international trade in food security is not clear, but it is important to analyze its effects scientifically instead of ideologically. Such analyses are necessarily incomplete, and the empirical evidence on the effects of increased international trade on food security is mixed. There are compelling theoretical reasons to believe that more international trade will improve food security outcomes in the long term, but pronouncements on the prospective effects of future trade agreements must be made with caution. International trade agreements are piecemeal and are implemented in countries with a wide range of economic conditions that may not conform to the simplifying theoretical assumptions of economic models.

Introduction

The purpose of this chapter is to consider how rural education, and rural schools more particularly, might contribute towards food security. The practice and policy context for this is Australia which, it is recognized, has points of distinction when compared to other countries. Notwithstanding, there are ways to generalize from the specificity of the Australian context, including through a set of principles for progressing an ethics of sustainability which are presented and considered later.

Why an ethics of sustainability? Why link it with food production, food security, and schools in rural contexts? Fundamentally because profiling an ethics of sustainability brings together critical matters of choice with regard to purpose, and principally *moral* purpose, and taking action to “do what is right, to do what is required” in the light of overwhelming evidence. Food production and distribution and security challenges confronting the globe underpinned by unprecedented population growth rates are an instance of overwhelming evidence *for something to be done differently*. Kurlansky’s deeply insightful and disturbing book on the biography of the cod and its demise overtime – “abundance turned to scarcity through determined short sightedness” (Kurlansky 1997) – epitomizes how a potentially sustainable resource has been pushed to the brink of extinction by an absence of an ethics of sustainability to inform and govern choices.

Schools and education are used to reinforce values and attitudes about national priorities as well as deal with emerging challenges and problems. Put another way, schools induct the young into society and nurture their agency; they are also used to “fix problems.” Drawing on nearly half a century in education working from preschool through tertiary levels, some illustrations are as follows: sex education to deal with sexuality and sexually transmitted diseases, consumer education to make students more informed consumers, environmental education to bring the natural world into the foreground of thinking and action, parent education for preschoolers to ensure children get a “better start to life,” and so forth.

Context and Dimensions

Australia comprises six states and two territories, each of which has an elected parliament as well as a national government. It has a population of 22.5 million, the majority of who live in the three most populous states – New South Wales, Victoria, and Queensland – and a land mass of 7.5 million square kilometers. Distance and very low population density are two of the dominant challenges of ensuring all children can access schooling. Under the Constitution, the states and territories are essentially responsible for providing and managing schools. In recent years though, the national government has played an increasingly important role in education, principally through its financial powers and by developing coalitions of support for national initiatives like the Australian Curriculum, the public release of school performance data, and literacy and numeracy testing.

There are approximately 9500 schools in Australia for 3.5 million full-time equivalent students from preschool through year 12. Direct responsibility for running schools is vested in the states and territories. As well, there are three main schooling sectors – government (6743 schools), catholic (1708 schools), and independent (1017 schools). Definitions of a rural school vary by jurisdiction and by sector. However, around 40–50% of schools are in nonurban locations in communities which vary in size from about 100,000 to less than 100. In some locations, schools are literally in the corner of a farmer’s paddock. Most rural schools are government because governments are required by legislation to ensure children can access education. As well, most rural schools are in close proximity to a primary industry and, in some instances, have direct engagement with primary industries through agriculture topics and farm practices, aquaculture projects, and courses which provide support services for primary industry enterprises like technology studies and economics. (There are also a few urban schools which have a direct link with food through curriculum specializations).

Food Security

Food security is inextricably linked to the principal social, political, economic, and cultural dimensions of a society and particularly to environmental health, well-being, and sustainability because of the fundamental connection between nature and food. Flannery argues that “[o]ur search for sustainability . . . [is] the greatest challenge we have ever faced” (Flannery 2008). Pretty’s focus on sustainability and agriculture foregrounds human activity as central to understandings of it and highlights “not damaging the environment” (Pretty 2002). Goldie, Douglas, and Furnass draw upon the Brundtland Report of 1987 for their definition of sustainability: “the capacity of human systems to provide for the full range of human concerns in the long term” (Goldie et al. 2005). Their definition accentuates imperatives for survival.

Food production and food security are not discretionary items of national policy or of national productivity. As Pretty argues, “[w]ithout food, we are clearly nothing. It is not a lifestyle or add-on fashion statement. The choices we make about food affect both us, intrinsically, and nature, extrinsically. In effect, we eat the view and consume the landscape. Nature is amended and reshaped through our connections – both for good and bad” (Pretty 2002). Put another way, “will there be sufficient nutritious food available for nine billion people by the year 2050?” (Persley and Blight 2008). The majority of the food consumed daily in Australia is produced in rural areas. To illustrate, the Murray–Darling Basin, while comprising only 14% of Australia’s land-mass, supports around 42% of Australia’s farms (Cullen 2005). Producing food, even where it has “gone the way of high tech,” still requires large numbers of highly skilled and semiskilled workers. Unlike mining, agriculture and horticulture are not as conducive to a fly-in/fly-out model of labor supply, even with the advent of agribusiness.

Ensuring that Australia remains a country that is food secure cannot be taken for granted. As Australia’s population grows and changes over time and the impacts of climate change “kick

in,” new problems and opportunities will emerge. These changes, and others that food production and distribution are reliant on, provide new policy development and program opportunities for rural education, rural educators, and rural communities.

Rural Education and Food Security

Exploring new relationships and partnerships between rural education and food production and security has the potential to build new understandings and practices about them and also arrest, or at least slow, the marginalization of rural education and rural communities in relation to contributing to Australia’s future. Rural education needs to partner with other essential human services like health services and local government and the private sector to address the challenges of ensuring that people who work in primary industries or who are directly impacted by the vibrancy and profitability of them can access high-quality education. As Allison concludes, following an analysis of the possibility of “‘ordinary’ landscapes or communities within which we live, work and educate”, to reinvigorate ways of shaping the future “sustainability [of food production] immediately shifts the perception of ‘ordinariness’ of these . . . landscapes” and opens the way to new possibilities (Allison n.d.).

Linking rural schools and rural education with food production and food security creates new spaces of opportunity of an intellectual kind as well as a locational and physical kind. Intellectual in the sense of “pushing the envelope” of the broadly accepted roles and functions of schools in society. Physically in terms of how the spaces provided for schooling in rural communities – classrooms, specialist learning areas, offices, playing fields, and so forth – might be enjoined in the “big project” of food production and food security.

Soja provides theoretical tools to assist with reconceptualizing the role and function of schools, of education in rural contexts. He argues that the preferencing given to social and historical perspectives on issues is key to understanding why space and spatiality are virtually absent

from critical discourse on major matters like food and food security (Soja 1996). Thinking differently about space and spatiality according to Soja may produce insights about phenomena, such as transforming rural schools to play a significant part in progressing food production and food security. This “thinking differently” Soja calls “Thirdspace,” “a purposefully tentative and flexible term that attempts to capture what is actually a constantly shifting and changing milieu of ideas, appearances, and meanings” (Soja 1996).

The central challenge of “Thirdspace” is to “begin to think about the *spatiality* of human life in much the same way that we have persistently approached life’s intrinsic and richly revealing historical and social qualities: its *historicality* and *sociology*” (Soja 1996). This is because, from Soja’s perspective, while it can be assumed that “rightfully” there will always be historical and social dimensions brought to bear on issues or problems, there *is* more. Integral to “Thirdspace” is an invitation to “set aside the demands to make an either/or choice and contemplate instead the possibility of a both/and also logic. . .” (Soja 1996).

Following are three brief case studies of rural schools in South Australia which illustrate various ways of engaging with local rural communities, food production, and education. For the Cowell Area School, it is aquaculture; for the Cleve Area School, broadacre cropping; and for Mypolonga Primary School, it is local horticultural produce coupled with tourism.

Cowell Area School enrolls students from pre-school age through year 12, the final year of secondary education in Australia. The school is located 500 km northwest of Adelaide (the capital of South Australia) in the township of Cowell which is situated on Franklin Harbour. The district population is approximately 1070, and at the time of writing, the school had an enrolment of 178. The school has a community library – as do all other area schools in the state – which serves the needs of students and adults of the community.

Over 20 years ago, it started becoming very clear that Cowell was essentially dying due to the impact of poor grain yields from drought and near-drought conditions and the added continuing drift of young people out of the town to greener

pastures. Sitting on the town’s doorstep, however, was a 49 km² pristine body of protected water, Franklin Harbour. There was also a local council keen to do whatever was necessary to save their town, a state government who was active in trying to support local communities take action, and a school leader willing to go beyond the confines of policy and established ways of being a school principal – ideal “raw materials” for a new venture in aquaculture.

The school’s website tells the story:

The Aquaculture Course at Cowell Area School has grown from an idea put forward by a group of local oyster growers to a structured course undertaken over two years of senior secondary schooling.

In 1991 Cowell oyster growers initiated contact with Cowell Area School and requested a course that would suitably equip students for entry into the Aquaculture industry. 1992 was spent developing a curriculum, in consultation with local oyster, yabby, abalone, and fin-fish growers, Department of Education, TAFE (Training and Further Education), AFA (Australian Fisheries Academy) and SAFITC (South Australian Fishing Industry Training Council).

The course was appropriate for the industry, while still maintaining the educational outcomes of a senior secondary program. The first course was offered in 1993 and has continued to grow to this day, with a 90% success rate of all students undertaking the course.

1999 saw the implementation of a full time farm manager (Tom Kenny) and a 0.5 time teacher to directly support students whilst in the classroom. Since 2000 the teaching position has been full time (1.0). Skills in aquaculture are gained through work placements within the industry, at the school’s oyster lease and fish farming tanks at the school.

Aquaculture in Cowell is now a major local industry with an annual turnover of around \$5 million and employing 40 or more people. These achievements are due in no small way to the preparedness of the school to respond very positively when first approached about playing a formative role in providing skilled workers. Over time, aquaculture courses available at the local school have changed to place greater emphasis on sustainability and particularly sustainable technologies. Critical to achieving these changes has been school leaders who have embraced a vision of education in a rural community as being more than just what happens inside the school fence. The success of Cowell Area School’s engagement with aquaculture has been the catalyst for other schools in the region to review their programs and develop options and pathways for youth to transition into marine environment food production. (<http://acacia.cowell.as.sa.edu.au/cms/>)

Cleve Area School is located on the Eyre Peninsula approximately 600 km from the capital of South Australia. It provides education for students from entry through year 12 and has an enrolment of around 350 students. While providing local and district students with a broad and high-quality general education, the school also specializes in agriculture from years 10 to 12 with an emphasis on dryland farming. The school's website provides the following information on the specialization:

The Cleve Area School Certificate in Agriculture Course is offered to year 10, 11 and 12 students attending the school. Students can enter either at year 10 or 11 and will require a minimum of 2 years to complete the required Certificate II or III competencies.

The Cleve Certificate is delivered entirely at Cleve Area School's Sims Farm by Cleve Area School and Regional Skills Training (RST) Pty Ltd. (Registered Training Organisation) staff. The course is nationally accredited, under the Australian Qualifications Framework.

The course prepares students for the following:

- Tertiary study in the field of Agriculture;
- Direct entry into the workforce;
- And/or further vocational training (e.g. Cert III & IV courses offered by Technical and Further Education, TAFE, or other Registered Training Organisations, RTOs).

The course does this by offering students both South Australian Certificate of Education (SACE) subjects and competency based learning. These dovetail together such that students gain one SACE unit for every 70 h of learning in the Certificate II & III.

Cleve Area School's 400 Ha Sims Farm is used extensively to deliver the course. A self-replacing merino flock, prime lamb, and cereal cropping enterprises are run and studied by the students at Sims Farm. Students carry out as many of the day to day tasks involved in these as possible, and learn to shear and crutch sheep. Students also have 'ownership' of a paddock where they plan

and implement the cropping year by operating all of the necessary machinery (tractors, GPS guidance and mapping programs, airseeder, boomspray, harvester).

Workshops, day excursions, and guest speakers (from farmer groups, Primary Industries and Resources South Australia (PIRSA), Agribusinesses etc.) are accessed as 'opportunities' arise. These provide excellent learning opportunities for students and an excellent way for students to build personal links with their future peers.

Camps are another highlight which aim to expose students to a broader range of agricultural environments and enterprises. In recent years year 11 students have travelled to New Zealand's south island, Northern Territory (Katherine and Darwin regions), Victoria's Wimmera district, South East, Northern SA's station country and Rangelands, Mid North & Barossa, and Kangaroo Island (<http://acacia.cleveas.sa.edu.au/cms/>).

Note: certificate levels are based upon the Australia Qualifications Framework which covers all formally recognized national education and training certification from entry-level workforce (Certificate I) to doctoral level.

Studying agriculture – food production and food security – at the Cleve Area School “comes alive” because of high-quality teaching and through the school's “state-of-the-art” model farm which is based upon sustainable dryland practices. It is also assisted by the school having a boarding facility so students from outside the district can take the program.

Since 1975, there have been well over 400 graduates from the Cleve Area School Agriculture program. An estimated 60% of these graduates have stayed in the district to work on farms or in agribusinesses. A further 20% have gone onto tertiary education, and another 20% returned to their out-of-district farms and other employment. The Cleve agriculture specialization directly supports a multimillion dollar broadacre farming enterprise and through this, employment in a wide range of commercial businesses and human services.

Mypolonga Primary School opened in 1916 and has an enrolment of 130 students. It is located in a fruit growing and dairy district near the banks

of the River Murray, Australia's largest river. The school has a shop which is the centerpiece for its community engagement around food and food products as well as other things. The website continues:

The School Shop started in 1994 in the disused Post Office across the road from the school. Originally selling student-made crafts, we quickly realised when a bus tour from the then Proud Mary, now Murray Expedition Paddle Steamer added the Shop to its itinerary, that we needed to source high quality, locally made crafts. (The students also make locally sourced dried fruit confection and sell jams and preserves on consignment.)

We sell locally made crafts, taking 20% commission. Each class also makes their own produce. The Junior Primary class makes book marks, the Lower Middle Primary makes fridge magnets, the Middle Primary makes recipe books and the Upper Primary makes chocolate coated apricots and home-made lemon cordial.

We, the students are responsible for all financial record keeping. With a turnover of \$15,000 per year and over 30 consignors, we work hard to balance the books. We learn a lot about providing customer service, balancing the books and always improving what we do (<http://mypolongaps.sa.edu.au/wp/>).

Essentially, year 6 and 7 students (the final 2 years of primary school) engage with local people, as well as a few suppliers from the metropolitan area and some other schools in the district, to acquire stock for the shop, sell it, and ensure that suppliers are paid when their goods are sold. Profits go into school funds for special projects. Each student involved in the shop initiative is required to keep a computer inventory for each of their suppliers. They are also required to rotate through the various jobs of opening and running the shop, for example, greeting the tourists when they arrive each week, presenting them with complimentary samples to encourage purchases, ensuring shelves are well and attractively stocked, accurately counting and recording takings, and keeping the garden associated with the shop in good shape. Students are assessed on each of these tasks.

While the school's direct income may be modest by some scales, by others it is very significant. It is certainly very significant for the Mypolonga school and community because in and behind the dollars are countless stories that build and sustain

relationships across age groups and with people from the four corners of the globe and provide an "edge of difference" about what makes "our town and why we want it to endure." As Wheatley and Kellner-Rogers assert, "[t]he future of community is best taught to us by life" (Wheatley and Kellner-Rogers 1998).

Discussion

Rural contexts have evolved and changed over time and will continue to do so. Looking forwards, there will need to be "an openness to ruralities that are quite different from those we are familiar with" (Cocklin and Dibden 2005). The capacity to accelerate the speed at which the evolution and change of rural contexts occurs has been dramatically increased through globalization – especially via ICT, interconnectedness, acceleration, dis-embedding, and standardization (Eriksen 2007) – and through the continued growth of the world's population. The pressures these place upon the ways that community functions and on the environment, finite resources and relationships at a multitude of levels, are profoundly significant. The changes require – demand – a radical reframing of the role rural education, and rural communities might play in nation building and nation sustaining through food production and food security.

Education is a powerful and pervasive resource for perpetuating and for changing ways of thinking and perceiving, ways of being, and ways of doing and responding. Rural schools function as they do because of a complex mix of legislative requirements, policies, established practices, and expectations about "what schools should do." The "givenness of schools," however, is constructed and therefore is "open" and "available" for change. Put another way, rural schools are as they are because of a long history of decisions, and they would have been different than they are had different decisions been taken. Or in the words of Lefebvre quoted by Soja "(t)here is always Other" (my emphasis) (Soja 1996).

Transforming rural schools to become active agents in food production and security and

championing ethics of sustainability, either directly through primary production or via designing, teaching, assessing, and accrediting courses which prepare youth for careers in primary production and associated areas, are major undertakings. The undertaking falls most directly to school leaders. Staying with Soja's theorizing, the primary challenge is to embrace the pursuit of *Other*. Doing this requires rural educational leaders spending time creating and seeking out opportunities that have the potential to disturb and shift the status quo towards some other state which they, and desirably others, believe is likely to be more beneficial for students, staff, and the community *and* the "big agendas" of food production, food security, and sustainability.

School leaders need to do this in many different ways including by questioning, by influencing meeting agendas, by developing links and alliances within and beyond the school, by moving around and through the school picking up clues, and by making suggestions as to "what might be done instead." They also need to create and seek out opportunities that have the potential to shift the status quo by sharing images they have about the purpose and essence of education and by projecting a sense of control blended with a preparedness to enter into collaborations with others. As well, they need to draw upon the experiences and advice of colleagues and community and use various ways for reducing multidimensional possibilities into "manageable bits" to progress schooling transformations which contribute to overall deeper engagement with food production and food security efforts.

Principles which frame the global challenge and imperative of sustainability in light of the growing pressures on the planet, primarily through population growth, are also a resource for transforming rural schooling towards producing explicit learning about and for food production and food security. Principles "capture" the essences of issues and challenges and help to scope dimensions and complexities. They serve as bridging agents between the "big picture" and local contexts and provide indicators of the specific work required in order to change policies and practices. As well, principles are a basis for taking

the content of a particular context, evaluating and assessing the merits of them and then generalizing to other situations.

The following are principles that could help the transformation of rural schooling as being advocated:

1. The sustainability of rural contexts and communities and those who live and work in them is central to sustainability nationally and globally.
2. Rural contexts and communities require a productive blend of internal (or endogenous) and external (or exogenous) factors and resources to influence and facilitate sustainability.
3. Human services which are available, accessible, affordable, acceptable, and adaptable, at a local community level, are essential for the sustainability of rural contexts and communities.
4. Resourcing of human services for rural contexts and communities is an investment in sustainability.
5. Sustainability is more likely to be optimized when interconnections between human, natural, institutional, produced, and social forms of capital are recognized and used.
6. Sustainability is more likely to be optimized when government funding and accountability requirements are able to flexibly transcend portfolio boundaries.

As argued at the 2008 National Community Education Association in Dallas, Texas, rural schools are complex organizations, and processes of change, especially ones that challenge schools and school leaders to step outside conventional ways of functioning, can disturb and disrupt "taken-for-granted" patterns of behavior. For instance, what happens during a financial crisis when depositors withdraw their funds and trust in banks, so too a community can withdraw its support of a school if it is being seen to be not paying attention to "core business" – children and their learning. Using schools as a platform for progressing deep engagement of students in food production, food security, and the ethics of sustainability requires leaders to work across several

change fronts simultaneously and iteratively. This in turn means that rural educational leaders need to know and understand deeply the cultural contexts – or as MacGilchrist, Myers, and Reed would say, they need “contextual intelligence” (MacGilchrist et al. 2004). They also need to have a sound grasp of the main elements of school operations that, in essence, “define” what a school is and what sustains the work of a school and indeed that single a school out from all other organizational forms. Of primary importance, here are curriculum, pedagogy, care of and relationships with students, relationships with parents and community members, concern for standards, and concern for a school’s credibility.

In a book of contributions on the future of leadership by various authors, written to celebrate the life and work of Warren Bennis, Bennis has the privilege of authoring the final chapter. His last words in the chapter are especially pertinent for rural educators and leaders and the educational challenges of food production, food security, and the ethics of sustainability. While acknowledging how history had influenced his career, he particularly emphasized the power of “the spirit of *place*” (Bennis et al. 2001). This is a fundamental challenge for rural leaders, rural schools, and rural communities in pursuit of new purposes and realms of operation – to discern and harness the “spirit of *place*.”

Summary

Schools and education are used to reinforce values and attitudes about national priorities as well as deal with emerging challenges and problems. Put another way, schools “fix problems.” This chapter considers how rural education and rural schools more particularly might contribute towards food security and an ethics of sustainability. To do this, three brief case studies of rural schools which are engaged in various forms of food production education are presented and discussed. While the practice and policy context is Australia, principles for progressing an ethics of sustainability incorporated in the chapter are a basis for generalizing to other places.

Synonyms

Anti-hunger work; Emergency food; Food access; Food insecurity; Food justice; Food policy councils; Food sovereignty; Hunger; Right to food; Social and spatial contexts of food insecurity

Introduction

Food security has become an increasingly prominent topic in the last four decades, given escalating concerns related to volatile food prices, climate instability (and related crop unpredictability), and losses of resilience in agro-ecological and institutional food systems related to the restructuring of global agri-food regimes. While the most austere definitions of food security equate being food secure with the availability of some number of calories, more systemic definitions describe food security as being “a situation in which all community residents obtain a safe, culturally acceptable, nutritionally adequate diet through a sustainable food system that maximizes community self-reliance and social justice” (Hamm and Bellows 2003, p. 37).

As the flagship organization attempting to coordinate international efforts to address hunger, the Food and Agriculture Organization of the United Nations has provided a central forum for discussions of food security, nominally since the inception of the World Food Programme in the early 1960s and the World Food Summit of 1974 (see also “Food Security”). In this debut on the world stage of anti-hunger politics, food security

was defined as the “availability at all times of adequate world food supplies of basic foodstuffs to sustain a steady expansion of food consumption and to offset fluctuations in production and prices” (FAO 2003). Since that time, and the creation of the Committee on World Food Security as an intergovernmental body for developing and reviewing food security policies, the term’s meaning has been heavily contested, challenged, and transformed. The FAO’s accepted definition has changed multiple times in response to the complexity confronted in attempts to ensure food security through development (World Bank 2008). Similarly, the scale of assessment and policy has changed, from a focus on global and national scales to the household and individual. Current FAO food security approaches can be reviewed in the regular publication *The State of Food Insecurity in the World*, which has been published jointly almost every year since the 1996 World Food Summit by the Food and Agriculture Organization of the United Nations, the International Fund for Agricultural Development, and the World Food Programme to discuss underlying causes of hunger and malnutrition and monitor progress toward hunger reduction targets established at the 1996 World Food Summit and the 2000 Millennium Summit.

In the wake of the catastrophic failures of food markets to feed people adequately in 2008 and 2011 (partially under the stress of speculation in food commodities), a critical minority of discussions on food security have shifted away from charity-based food aid – and even away from entrepreneurial promotions of market access for agricultural producers – toward consideration of the structural conditions that enable or disrupt food security. Generally, in the postcolonial period, after modern governments were supposed to have vanquished vulnerability to famine, the persistence – and, in fact, rise – of hunger as what the World Food Programme calls “the world’s greatest solvable problem” has complicated approaches to food security that focus largely on caloric availability in favor of more systemic approaches (see also “Food Assistance and International Trade,” “Food Security and International Trade”). This shift toward systemic understanding

of food security has not only been from global to more local scales and from caloric sufficiency to *nutritional* sufficiency but also to an explicit emphasis on ensuring food security across time and the idea that food security should not be dependent on emergency food supply. Systemic approaches to food security focus not only on the prevention and amelioration of hunger, but on the challenges to the integrity of food cultures and moral economies posed by the commodification of food.

The following exploration of food security briefly touches on the genealogy of the term's significant usage as well as some of the tensions around food security in agri-food practice and scholarship. It reviews key themes that help illuminate why this term has remained central to anti-hunger work while not entering public discourse in clear ways. It describes challenges involved in assessing what food security would mean and in securing it. It reviews paradigmatic analyses across a continuum of food security approaches. Finally, in the context of contemporary struggles over the legitimacy of different approaches to food security, commodification of food commons, and the right to food, this entry considers the relationship between the related strategies of food security and food sovereignty.

Understanding Food Security

As discussed in a few scenarios below, food security is a commonly understood concept, but one that is often understood in significantly different ways, leading to tensions over approaches to addressing food security and perhaps contributing to common underestimations of the persistence of food insecurity, even in wealthy societies and nations with food surpluses. Food security has been named as a human right in international governance regimes for over 50 years, most notably with the mention of food in the 1948 Declaration of Human Rights, and in other work of the United Nations, particularly via the programs and committees focused on food, described above, and more recently via the office of the UN Special Rapporteur on the Right to Food.

Despite decades of attention to food security named as such, as well as considerable official consensus about the desirability of including the right to food as an unalienable human right (see also “Right to Food in International Law,” “Food Security”), the concept remains a specialized one used mainly in professional circles related to hunger relief and community empowerment. A major report on *Perceptions of the U.S. Food System*, commissioned in 2005 by the Kellogg Foundation, identifies food security as one of a set of key ideas that “act as de facto, and sometimes deliberate and explicit, anchors of communications about food systems” (FrameWorks 2005, p. 61). The report concludes that the idea of “food security” is not well understood, like many paradigms used by specialists to describe food systems most people know well, at least in part, through everyday experience. Based on extensive public discourse research in the USA, the authors conclude that they (p. 6).

Are confident not only that the phrase is unfamiliar, but that it would strike people as puzzling, since they tend to feel little or no insecurity related to food. . . . In order to understand the idea of food security, in something like the way it is understood by experts, people would need to have more of a sense of the ownership of food production, who decides where and how to distribute food for sale, and how prices are set, for example.

They continue, highlighting how a lack of a conceptual understanding of food security means that (p. 7).

Members of the public are also unlikely to appreciate the different values messages offered by advocates which relate the food supply to democracy, community empowerment and social justice (related to redlining, for instance). Instead, given their current dominant patterns of thinking, people are likely to associate this term with safety against terrorism, food tampering or shortages – i.e. vivid, concrete and immediate types of danger that can easily be associated with food.

This emphasis on safety and protection is a common US distortion of the idea of “food security” as securing food from intentional or unintentional contamination, at all points along

the food chain. The FrameWorks study notes that this orientation toward security in everyday life makes people more likely to engage in defensive ignoring of food system problems than in cooperation to address the systemic problems that contribute to food insecurity.

If an emphasis on securing food against fear of contamination is one source of confusion stemming from the way that the concept of “food security” has been used in some discourses (most notably US government funding sources that provide grants for projects to secure food supply chains), security in the context of financialization has also entered popular vocabulary in the wake of the global financial crisis. Since the “security” as a financial instrument is not what is meant in the phrase “food security,” this form of food “security” is not examined here, except to note that such financialization of food appears to be an increasingly problematic threat to systemic food security, as the Institute for Agriculture and Trade Policy primer on Excessive Speculation in Agricultural Commodities explores in some detail.

In addition to further confusing popular understandings of “food security,” the successful propagation of both food safety and food financialization discourses underlines the tactical nature of food in political and economic domains: from war to colonialism to the maintenance of class hierarchies (or, in contrast, to the securing of sovereignty), control over means for securing sufficient food is a central necessity of social organization (see also “Land Acquisitions for Food and Fuel,” “Food Security and International Trade”). When considering the ethics of misunderstanding food security, it is useful to recognize how much efforts to ensure – as well as define – food security are bound up within state and industry politics as well as geopolitics. As scholars from the social sciences and humanities have pointed out, utopian expectations related to “technocratic fixes” to the problem of food insecurity, such as the Green Revolution (and its contemporary manifestations), often substitute for sustained engagement with the social organization needed to ensure food access (Cullather 2010; Hinrichs 2013).

Systemic Understanding of Food Security

Systemic approaches to food security start with the position that striving for food security requires not only addressing the acute or chronic experience of food insufficiency but also the broader *social* and *spatial* contexts that contribute to being either food insecure or food secure. Historically, food security measures by both national governments and the FAO focused on increasing the availability of food through production increases and grain reserves (see also “Poverty and Basic Needs”). Increasing food production is often touted as a remedy for starvation and a presumed guarantor of increased food security to be achieved, for example, via GMO use and agrochemical inputs to increase yields. Despite the logic of this approach to problems of acute and chronic food scarcity, though, work such as Amartya Sen’s on the causes of famine has shown that the relationship between food supply and food security is not straightforward: “starvation is the characteristic of some people not *having* enough food to eat. It is not the characteristic of there *being* not enough food to eat. While the latter can be a cause of the former, it is but one of many *possible* causes. Whether and how starvation relates to food supply is a matter for factual investigation” (Sen 1981, p. 1).

Such work has only slowly helped complicate public discourse about the importance of power in securing food by revealing that famines have historically occurred in times when food was available and abundant (Sen 1981; Davis 2000). This dynamic continues today, with high rates of hunger persisting (estimates suggest world food insecurity above 10%) despite contemporary production of more than enough food to feed the world population (even if concerns about future production keeping up with demand appear legitimate from many perspectives). Even in nations that stockpile row crops to buffer national sovereignty in cases of shortage (see also “Food Assistance and International Trade”), supply-side approaches do not necessarily translate into food security. Emergency grain rations may be caloric without being nutritious, and many people

(particularly farmers, for whom yield-increasing technologies have translated into lower prices for their crops) cannot afford even subsidized food. Commodification poses an ongoing challenge to food security because as food, a necessity, becomes a commodity it can only be exchanged for money, thereby creating disadvantages for those with less financial resources.

As Nick Cullather explains in his exploration of the political dimensions of the Green Revolution, “With its 20-million-ton buffer stock of grain to preserve self-sufficiency, India has more undernourished citizens than any other nation, some 213 million without enough to eat. The paradox of plenty continues to underscore the fallacy of addressing hunger exclusively as a supply-side problem” (2010, p. 266). Many of the world’s least food secure people (the “bottom billion”) are current or recent food producers – in this light, rural to urban migration into the informal urban settlements that are projected to house a quarter of the world’s population in the next two decades can be seen in terms of structural ways that food insecurity is related to existing social structures. In addition, a recent FAO report revealed that one third of the food produced globally is wasted or lost each year. This suggests that food shortage (production shortfalls), food poverty (inadequate food availability), and food deprivation (malnutrition) are not causal problems, but are rather manifestations of social and spatial organizations that prevent access to food (DeRose et al. 1998).

Historically, communities organized a variety of mechanisms to ensure secure access to adequate food in times of food scarcity. For example, in preindustrial England, the existence of “common” land ensured that peasants, “commoners,” had access to grazing land. With the expansion of capitalism, these “common” social institutions have been dismantled as part of a general process of commodification in which social and economic spheres became increasingly integrated and dominated by market relations, and extractive commercial interests in food production serve to systematically dismantle elaborate institutional supports for food security, such as state grain supplies and emergency distribution systems

(Davis 2000). For small farmers, particularly in poorer countries, commodification of farming inputs, such as seeds, also creates barriers to access.

In the postcolonial period, pressures to intensify commodification of public resources have grown with the increasing dominance of neoliberal policies since the 1980s. Neoliberal policies were pressed upon indebted nation-states by international lenders such as the International Monetary Fund and its structural adjustment programs (McMichael 2011). Neoliberal reforms espoused the efficiency of markets and the benefits of trade liberalization, while condemning the distortions of state interventions; in other words, the market was entrusted to deliver food security by endowing individuals with choices and by breaking down barriers to trade through deregulation and privatization. In practice, the neoliberalization of agricultural and food policies in developing countries encouraged their orientation away from producing staple food crops toward crops for export, leading to increasing dependence upon imports of staple products (see also “Economy of Agriculture and Food,” “Multifunctionality of Agriculture and International Trade”). Furthermore, the “free” trade doctrine has privileged Northern, industrialized countries at the expense of the rural poor in developing countries (Schanbacher 2010). Not only has this development strategy failed to deliver upon its promises, it has also led to increased food insecurity, as reliance on world markets exposes importing countries to spikes in food prices. Compelling research has now demonstrated that in response to the global food crisis of 2007–2008, countries with adequate food production, such as Mali, fared much better than countries like the Gambia or the Côte d’Ivoire, which are much more dependent on imports of staple crops (Moseley et al. 2010). However, adequate financial resources and sufficient food production at the national scale still do not guarantee food security for all communities, households, and individuals. In the USA, households headed by woman, as well as African Americans and Latinos/Latinas, experience food insecurity at disproportionately higher levels than the rest of the population (Heldke 2009).

In summary, systemic examinations of food security often focus on the way that institutions, particularly those that many argue are a central part of important social contracts around food, have been eroded or completely eradicated through the commodification of common property regimes, colonial expansion, and more recently, neoliberal erosion of state supports for agricultural and entitlement programs and other social safety nets. These processes do not impact all groups equally; divisions based on gender, race, and class continue to shape food security. In addition, war and other conflicts along with degraded environments all continue to pose significant challenges and obstacles to achieving food security worldwide (see also “Food Security”). As multiple scholars and food security activists have noted, narrow definitions of food security that do not consider these ongoing systematic challenges underestimate the structural dimensions that reproduce conditions of food insecurity.

The Challenge of Systemic Assessment

Even recognizing the importance of the way that social and spatial relations produce food insecurity for some, and food security for others, the dynamics of food security are very difficult to assess. DeRose, Messer, and Millman summarize this challenge in their review *Who's Hungry? And How Do We Know?* “Given the definition of hunger as consumption of a diet inadequate to sustain good health and normal activity, growth, and development, an ideal measure of hunger would involve a comparison between the diet actually consumed and that required for these purposes . . . however [one] encounters significant difficulties both in measuring or estimating the diet and in defining the requirements against which it should be compared,” not least because of the practical difficulty of measuring whether people are getting enough to eat and assessing what is “enough.” While food insecurity may have outcomes severe enough to be measured (such as death rates), standards of what normal or adequate “growth” or development are difficult to define, given the

wide range of possibility in healthy growth patterns (DeRose et al. 1998, p. 20).

Regardless of the complexity inherent within the concept of food security, what is often counted in assessments of food security is caloric intake, which is both easy to measure and emphasized by prevailing models of productivism in agri-food systems and allied paradigms of food aid. Although the FAO has developed more complex measurements of food security that attempt to integrate more subjective, qualitative, and also nutritional indicators (and to support food aid regimes that strengthen rather than undermine regional food security), systemic conceptualizations of food security that include social justice and sustainability are even more challenging to assess and evaluate. According to Hamm and Bellows (2003), a systemic approach requires that food security be assessed and evaluated through participatory research, which draws on community-generated knowledge to assess needs and formulate improvement strategies. Holistic measures and approaches that are defined by and for affected communities, in coordination with policy makers and researchers, have the potential to be both adjustable to each individual setting while providing information for cross-referencing between places.

The Food Security Continuum

Systemic action for food security builds beyond short-term emergency assistance to encompass long-term strategies to build a “sustainable food system that maximizes community self-reliance and social justice” (Hamm and Bellows 2003, p. 37). A prime example of a systemic approach across multiple scales and levels of food security is the Food Security Continuum, a framework developed in Canada and used by food policy councils and nonprofit organizations to identify and act upon both the immediate and long-term obstacles to achieving food security. The food policy councils and food security networks that use this continuum framework (e.g., of Alberta and Newfoundland and Labrador) demonstrate their systemic approach by asserting that “food

security is dependent on a healthy and sustainable food system” and committing to ensuring food security not only by providing emergency food aid but also by building capacity and adopting “systemic change strategies” in long-term food policy and activism. This three-part system also bears some resemblance to the three paradigms of food security Lisa Heldke laid out in her 2009 critical analysis of the central conceptions of food access: charity, co-responsibility, and rights. The following section outlines this three-pronged approach with illustrative examples and briefly discusses some tensions related to these various dimensions of approaches to food security and their integration in something like a “continuum.”

Charity, Emergency, and Short-Term Relief Strategies

By far, the most dominant approach to hunger relief and food insecurity is the charitable distribution of food through food banks, international donations, and other voluntary means (see also “Food Assistance and International Trade”). Although charity may provide necessary immediate relief, it is problematic because it empowers the giver with a sentimentally satiated sense of *noblesse oblige*, and it signals that “benevolent gifts are just that – gifts – benefactors labor under no obligation to include recipients in decisions about the form gifts should take” (Heldke 2009, p. 216; Poppendieck 1999). In addition, charitable giving by itself does not address the causes of food insecurity. Consequently, although perhaps acutely motivating, charity will always be insufficient without capacity building at multiple scales as well as efforts to work for systemic change.

Nevertheless, some relief initiatives framed as charity might cultivate capacity building in the long term. For example, in the wake of Hurricane Sandy on the east coast of North America in late 2012, millions were left without power, water, heat, and adequate supplies. Tens of thousands were left homeless, but established disaster-response organizations were unable or too slow to take adequate care of the vast affected area and its population. Occupy Sandy, an outgrowth of Occupy Wall Street, was collaboratively

developed to provide warm meals, distribute supplies, and organize volunteers for assistance and cleanup activities. Although explicitly providing charity in the face of acute necessity, like much food security work, this initiative spurred capacity building, as volunteers got involved, as well as a systemic critique of existing state and non-governmental organizations and their failure to ensure food security.

Capacity Building and Co-responsibility

A focus on capacity building sheds light on the fact that achieving food security relies on creating and sustaining social organizations that respect the integrity of food cultures. Capacity building can occur at a variety of scales, connecting *across* scales as systemic approaches recommend – potentially constructing relational dynamics that evoke the co-responsibility by both individuals and society for food security called for in Heldke’s analysis (2009). In the USA, the community food security movement has been instrumental at mobilizing community-scale changes in food policy since the demise of most remaining federal supply management programs in the mid-1990s (between 1994 and 2012, the Community Food Security Coalition provided a focal bridge in the USA between grassroots organizers, non-governmental organizations, foundations, and government community food security programs as a broad membership-based organization). However, an ongoing problem with capacity-building work related to food security initiatives has been that people who disproportionately experience food insecurity have been “the objects of [food security] work but not the leaders of it” (Slocum 2006, p. 330). In the USA and elsewhere, community food security initiatives risk replicating the institutionalized racism prevalent in the dominant society and the agri-food system by acting with disregard to the power and persistence of racism and white privilege (Slocum 2006), particularly when they are allied with charity models. Not only does this social dynamic encumber food security, it disregards the relationality and webs of dependence that forge the food system, producing its variegated outcomes of food security for some and insecurity for others

(Heldke 2009). Privilege and racism are relationally produced, and therefore, confronting them while building capacity for food security requires a cultivation of Heldke's paradigm of co-responsibility between people and places, as well as an antiracist practice that strives to eradicate systems of oppression and exclusion (Slocum 2006). Such critiques bring attention to how initiatives that frame and practice food security have implications for their capacity to generate change.

One of the most successful and well-publicized food security initiatives is the capacity-building system organized at the urban scale by the government of Belo Horizonte, Brazil (Rocha and Lessa 2009). With the goal of providing access to healthy food for all residents, reducing rural to urban migration due to rural impoverishment, and equitable community empowerment, this municipality has conducted a multifaceted program over the past two decades, including a number of subsidized "popular" restaurants that have served up to 5500 inexpensive and healthy meals a day, nutrition programs in schools, subsidized food baskets of nonperishable goods, support for farmers' markets and alternative modes of distribution, and urban agriculture programs (Rocha and Lessa 2009). At the national scale, Brazil has built on this model to create a National System for Food and Nutrition Security, "SISAN, through which the State, with the participation of organized civil society, will formulate and implement policies, plans, programmes and actions towards ensuring the human right to adequate food" (quoted in Rocha and Lessa 2009, p. 397). This initiative has prompted replication across Latin America and, particularly because of the ways that it navigates the complex and interwoven dynamics of charity, co-responsibility, and rights, has increasingly been taken up as a model for other broad regional efforts (e.g., in Africa) highlighted extensively by the UN Special Rapporteur on the Right to Food, De Schutter, who, since his appointment in 2008, has been a constant promoter of the systemic links between agroecological food production systems and the right to food.

System Change Strategies and Rights

The basic premise of the food system interventions in Belo Horizonte involves making food a basic right by providing many ways to access food and by promoting food-based livelihoods, confronting some of the limits of the commodification of food by providing some level of food security as a common benefit. By integrating key aspects of food production chains (small-scale rural production livelihoods, rural-urban linkages, food distribution, preparation, and service, both direct and through institutions), this model echoes the aspirations of the Food Security Continuum in strategically using responses to food security needs, charity impulses, and politicized rights discourses to effect systems change across a range of scales.

The much analyzed negotiation between participatory decision making in these examples and the determination to legitimize rights to food regardless of demonstrated worthiness addresses some of the limitations Heldke notes in her critique of rights-based as well as charity paradigms (2009, pp. 219–220). Robust trends suggest that popular attention will continue to focus on food price volatility, projected production shortfalls, food aid, land grabs, and the political economy of who controls the scale and scope of food provisioning and the policy that governs it. Both in wealthy countries, where the control of food has been extensively protected from market forces by policy and cultural norms, and also in poorer countries that have been subject to dramatic price fluctuations and labor regime shifts of contemporary food market regimes, individuals and societies struggle to come to terms with neoliberal efforts to continue to transform collective rights into individual rights and also to face the ramifications of opening to market dynamics the control of food (McMichael 2011). Alternative agri-food scholars point out tensions involved in rhetorics of free trade by nations with protected food economies, as well as in the significant emergence and institutionalization of support for common moral economies that value food security in a range of ways beyond their economic value as commodities (Thompson 1971; Cullather 2010; Hinrichs 2013).

Conclusion: Moral Economies and Ecologies of Food Abundance and Scarcity

As a concept, food security potentially helps denaturalize hunger as inevitable by highlighting the social and spatial organizations that can promote or prevent food security. The concept can also be used to empower and illuminate alternative modes of social organization that help to maintain food security even in situations of scarcity (Thompson 1971; DeRose et al. 1998; Cullather 2010). A systemic approach to food security requires looking beyond food procurement to consider the food system holistically, in order to enact “sustainable community food production, processing, and availability” (Hamm and Bellows 2003, p. 42).

Various conceptualizations have been proposed to guide systemic thinking about the food system and to provide a pathway for change. Since the 1990s, food sovereignty, defined as “the RIGHT of peoples, countries, and state unions to define their agricultural and food policy without the ‘dumping’ of agricultural commodities into foreign countries” (Schanbacher 2010, p. 54), has emerged as a powerful conceptualization to counter the dominance of limited, economic, and paternalistic understandings of food security at the global scale. The growing global movement for food sovereignty prioritizes the values of sustainability; attention to social and power relations between producers and consumers, particularly at local and regional scales; and the rights of small-scale and indigenous farmers and peasants, especially to access productive resources. The focus on rights and entitlements differentiates food sovereignty from even the most progressive articulations of food security (and food justice), which focus centrally on ensuring food access. In fact, food sovereignty was articulated, in part, as a critique of dominant narratives of food security, especially those utilized by the World Bank and other international institutions.

Some of its proponents have argued that food sovereignty promises a more radical conceptualization in framing food system change and therefore holds the greatest potential in unifying movements and achieving systemic changes to

the food system. Systemic approaches toward food security (Hamm and Bellows 2003) are not incompatible with food sovereignty, suggesting that both could be used in a complementary manner as they articulate with systemic contexts, especially as agroecological methods are gaining respect as legitimate (if not always profitable or large scale) means for successfully ensuring global food security (see also the International Assessment of Agricultural Knowledge, Science, and Technology for Development).

Summary

This exploration of food security briefly touches on the genealogy of the term’s significant usage, as well as some of the tensions around food security in agri-food practice and scholarship. It reviews key themes that help illuminate why this term has remained so central to anti-hunger work while not entering public discourse in clear ways. It describes challenges involved in assessing what food security would mean and in securing it. It reviews paradigmatic analyses across a continuum of food security approaches. Finally, in the context of contemporary struggles over the legitimacy of different approaches to food security, commodification of food commons, and the right to food, this entry considers the relationship between the related strategies of food security and food sovereignty.

Scholars have demonstrated that food security has not been a problem of food supply, but of access. Multiple processes contribute to food insecurity, such as commodification of food commons and the dismantling of social institutions that supported food security, as well as social exclusion, marginalization, and alienation from foodland. Considerable scholarly effort has helped critically support work on food security, encouraging efforts to secure food access to move beyond the provision of emergency rations to address the systemic processes that prevent food security by building capacity through social institutions, understanding the relational processes that confer values to food, and negotiating across the many different cultures represented across any food system.

Introduction

Despite decades of policies aiming to address hunger and rural poverty, these two challenges are still among the most acute problems that humanity is facing today and will face in the near future. Decades of official work on poverty reduction without major results led to the recognition and consensus that policies aimed at effective poverty reduction must address the needs of people in rural areas. But what are those needs and how are they met? Different worldviews and paradigms exist that propose different options to address the problem of hunger and rural poverty (Rivera-Ferre 2012), which result in different, often opposite, models. At the two extremes, we find a market-oriented dominant model of large-scale, capitalist, industrial, and export-based agriculture (Friedman and McMichael 1989) and the so-called alternative food systems and people-centered emergent models, based on agroecology principles of participation and collective management of resources, in which (radical) democracy is placed as a core element (Calle et al. 2011). Under the umbrella of alternative food systems, normally promoted by social movements, many different options and discourses exist (Constance et al. 2014), but they all have in common to emerge as counterproposals to the current capitalist food system and their vision that other practices and policies can reduce or eliminate global hunger. These new proposals understand that the problem of hunger and poverty is in fact a problem of inequity and power unbalance throughout the food system. The people's struggle for food sovereignty is a paradigmatic example. Food sovereignty is commonly described as "the right of peoples to healthy and culturally appropriate food produced through ecologically sound and sustainable methods, and their right to define their own food and agriculture systems" (Nyéléni Declaration 2007). As a political demand articulated around the prevailing industrial agri-food system, food sovereignty exemplifies the consideration of food as a means for social change, being also conceived as a counterproposal to the mainstream development paradigm (Rivera-Ferre 2008). In this manner, it breaks the traditional north-south

development paradigm to address development as a clash of models (Rosset 2003) asking for democratization processes and a fair distribution of resources in food systems.

Historical Background, Definitions, and Evolution of the Food Sovereignty Proposal

Food sovereignty is a dynamic concept in constant evolution. Since it was first proposed in 1996, it has evolved with the transformation of the international context and its adoption by a global network of social movements and civil society organizations (CSO) to include the interests of a wide range of collectives and, at the same time, adapt to different local contexts. It emerged from social movements as a counterproposal to the capitalist logic of the food system and the worldwide acceptance of neoliberal policies being implemented since the early 1980s. During that period two opposite trends occurred: on one hand, globalization and economic liberalization and, on the other hand, a social global movement raising the voice of alarm against this phenomenon, which began to expand and culminated in Seattle in 1999. One of these groups was La Via Campesina (LVC), a fundamental piece in the construction of the food sovereignty proposal.

The concept of food sovereignty became public at the International Conference of LVC in Tlaxcala, Mexico, in April 1996 and launched at the World Food Summit in Rome in November that year. LVC approved to send representations to the Technical International Conference on Phylogenetic Resources in Leipzig (Germany) in June 1996 and to the World Food Summit, as well as to the parallel forums of the civil societal organizations. The aim was to encourage NGO and CSO to discuss alternatives to the neoliberal approaches to reach food sovereignty, defined then as "the right of every nation to support and develop its capacity to produce its own food, crucial for the national and community food security, while respecting the cultural diversity and the diversity of production methods." This origin explains why

the first concept of food sovereignty was centered on the right of nations and on producers.

During the World Food Summit, LVC presented a series of principles that could act as alternative to the world trade policies and that would facilitate the attainment of the human right to food. In the declaration "Food Sovereignty: a future without hunger," they stated that "Food Sovereignty is a previous condition for a genuine food security" and therefore the right to food can be seen as the tool to achieve it. In 2001, the final declaration of the World Forum on Food Sovereignty in La Havana (Cuba) described five main action axes (La Via Campesina 2001):

1. Access to resources: food sovereignty promotes and supports individual and community processes to ensure that small- and medium-size producers have access to and control of basic natural and social resources. It includes proposals regarding access to land, seeds, financial services, water, or public services. The access to (and management of) resource proposal includes sustainability, indigenous rights, and gender perspectives as crosscutting dimensions.
2. Production model: food sovereignty fosters local and family production. It proposes a diversified production model based on local and traditional knowledge. The production systems must be sustainable and culturally appropriate to their unique circumstances. It supports endogenous development processes and the right to produce food.
3. Transformation and commercialization: food sovereignty defends the right of farmers, landless agricultural workers, fishermen, pastoralists, and indigenous people to sell their food production to feed local populations. This requires protecting and regulating the national agricultural and livestock production, shielding the domestic market from the dumping of agricultural surpluses and low-price imports from other countries, and promoting direct commercialization from producers to consumers.
4. Food consumption and right to food: food sovereignty defends the right of citizens to safe, nutritious, and culturally appropriate food. This food should be produced by local producers with agroecological techniques.
5. Agricultural policies and CSO: food sovereignty places producers and consumers at the heart of public policies related to the agri-food system. This requires strong organizations of peasants and civil society in general, promoting participation and radical democracy.

The food sovereignty concept has been evolving over time since its establishment. However, most of the definitions proposed comprise marginal differences and share the core principles: "Food Sovereignty principles of La Via Campesina." The International Planning Committee for Food Sovereignty (IPC) in 2002 defined food sovereignty as:

the right of peoples, communities and countries to define their own agricultural, labour, fishing, food and land policies, which are ecologically, socially, economically and culturally appropriate to their unique circumstances. It includes the right to food and to produce food, which means that all people have the right to safe, nutritious and cultural appropriate food and to food-producing resources and the ability of sustaining themselves and their societies.

In 2007, however, La Via Campesina redefined food sovereignty on the Declaration of Nyéléni (Mali) as:

the right of peoples to healthy and culturally appropriate food produced through ecologically sound and sustainable methods, and their right to define their own food and agriculture systems. It puts the aspirations and needs of those who produce, distribute and consume food at the heart of food systems and policies rather than the demands of markets and corporations. It defends the interests and inclusion of the next generation. It offers a strategy to resist and dismantle the current corporate trade and food regime, and directions for food, farming, pastoral and fisheries systems determined by local producers and users. Food sovereignty prioritizes local and national economies and markets and empowers peasant and family farmer-driven agriculture, artisanal - fishing, pastoralist-led grazing, and food production, distribution and consumption based on environmental, social and economic sustainability. Food sovereignty promotes transparent trade that guarantees just incomes to all peoples as well as the right of consumers to control their food and nutrition. It ensures that the

rights to use and manage lands, territories, waters, seeds, livestock and biodiversity are in the hands of those of us who produce food. Food sovereignty implies new social relations free of oppression and inequality between men and women, peoples, racial groups, social and economic classes and generations.

From the Nyeleni meeting it was agreed that food sovereignty focuses on food for people, values food providers, localises food systems, puts control locally, builds knowledge and skills and works with nature. As it can be observed, the latter definitions do not focus only on the right of nations, but rather on the right of peoples. It also introduces other actors widening the focus to not only producers and evolves from the recognition of women role to a more feminist and broad social justice approach proposing the end of any kind of oppression and inequities. It can be inferred from the above definition that food sovereignty serves as a political tool to address environmental, social, economic, and health issues; it is a guideline, or aspiration, in terms of a direction to be heading in and, hence, encourages continuous steps toward shortening the food supply chain and empowers both peasants and consumers. Notwithstanding the source of definition, the food sovereignty concept always refers to both the right to food and the right to produce, including the Declaration of the Rights of Peasants. In that manner, the proposal recognizes that people all around the world must have access not only to safe, nutritious, and culturally appropriate food but also to the resources and mechanisms for its production in order to support themselves and their societies (Declaration of Nyéléni 2007). Being a proposal developed in the context of the Global South, its evolution toward a counterproposal to capitalist agriculture and neoliberal policies has prompted interest in higher-income settings (Di Masso et al. 2014).

Thus, as the environmental and policy contexts have been changing, as well as other movements have joined the proposal, more dimensions have been added to the food sovereignty concept, including issues such as climate change (framed as a global ecological crisis), rural–urban migrations, rights of rural workers, or the situation of

youth and rural women. Another important evolution of the concept has been its increasingly politicized confrontation with neoliberal policies at the same time that agrobusiness expanded in the form of new enclosures (e.g., land grabbing, GMOs and bioprospecting, infrastructures, and value chains but also immaterial aspects such as the imposition of “monocultures of knowledge” and rationalities). These confrontations have crystallized in territorial disputes between what have been called “the spaces of domination” and the “spaces of resistance” articulated around local social and peasant movements which are actively resisting and defending their land and territories and themselves, in social, economic, political, cultural, and ideological terms (Rosset 2011; McMichael 2014).

The topic has also been explored under feminist approaches addressing the gender implications of power and control relationships within the food system (Patel 2012); peasant women’s contribution to the evolution of the proposal (Desmarais 2003, 2007), in both cases visualizing a convergence among the peasant and feminist global social movements; or the impact of public food safety regulations (McMahon 2011). Finally, food sovereignty addresses the need for social change with a focus on the governance of food systems. One major claim is that decisions on agri-food policies must be taken at all appropriate levels, placing poor peasants at the heart of food systems and demanding the *right to have rights* (Edelman and James 2011; Patel 2009). It is important to remark that at present, multilateral institutions such as UNEP, FAO or the Commissioner of the Right to Food, and governments (Mali, Nepal, Indonesia, Ecuador, Bolivia) have acknowledged its potential in the development of sustainable food systems, some of them including the proposal within their constitutions.

Right to Food, Food Security, and Food Sovereignty

From a global perspective, probably the best known proposals to address the problem of hunger are the right to food, food security, and food

sovereignty. They all have the same objective, but they are different both in terms of what they propose and their juridical status.

The right to food consists on the recognition of an individual and basic human right contemplated in the Article 25 of The Declaration of Human Rights in 1948. Its acknowledgment established a conceptual and legal framework that allows citizens to demand respect, protection, and safeguard for their needs to access adequate and sufficient sources of food. The Committee on Economic, Social, and Cultural Rights in its General Comment 12 defined that (1999) "The right to adequate food is realized when every man, woman and child, alone or in community with others, has physical and economic access at all times to adequate food or means for its procurement." According to Windfuhr (2002), the right to food empowers oppressed communities and individuals against the state and other powerful actors. The state should provide an environment that facilitates the implementation of these responsibilities assuring that all members of society, individuals, families, local communities, civil society, as well as the private sector, have responsibilities in the completion of the right to adequate food.

Alternatively, food security stands as a technical concept that attempts to address issues related to the access to food at either country or regional level, for instance, access by food-deficient countries to surplus products, import and export quotas, food aid, agricultural techniques to increase production, and irrigation. "Food security exists when all people, at all times, have physical, social and economic access to sufficient, safe and nutritious food that meets their dietary needs and food preferences for an active and healthy life" (World Food Summit 1996). There are a series of differences between these two related concepts. First, food security is not legally obliged to state which mechanisms could be used by malnourished people to protect themselves against the denial of their access to food. Furthermore, food security focuses on global, national, or regional availability of food, rather than individual access to food (Windfuhr 2002). Food security does not set any priorities when it comes to the

implementation of policies, while the right to food debates on access to productive resources and incorporates a particular set of rules and regulations for states with regard to people living in their territory, but it also includes extraterritorial obligations.

While both previous alternatives are improving steps toward solving the problem of hunger, they remain limited by a series of constraints that are covered by the concept of food sovereignty. For example, while food sovereignty also delineates access to productive resources as the right to food does, it goes further by including more precise policy proposals that define the access and control of resources to produce food. Furthermore, food sovereignty poses political challenges, which require that states regain the necessary policy space to conduct their fight against hunger and to be able to implement fully their obligations to their citizens in ensuring both their right to adequate food and other human rights (Windfuhr and Jonsen 2005). Finally, while both the right to food and food security emphasize the economic access to food, food sovereignty can be considered, in short, a policy framework for an alternative model of society.

Conclusions

The people's food sovereignty is a bottom-up political proposal to address hunger and poverty which has evolved since it was first conceived by the international peasant movement to become a counterproposal to capitalism. Since 1996 to now, it has included not only the needs of those who produce or collect food, but it also addresses core principles of equity, social, and ecological justice. Still, it is a concept that from the academic perspective raises some questions and critics, including whether the democratization of food systems would lead or not to food sovereignty, or how the peasants organized in a global organization can be framed within the traditional social class categories or if new theoretical developments in this sense are needed. In 2013, the ISS organized the conference "Food Sovereignty: A Critical Dialogue" where some of these topics were discussed.

Introduction

“Food sovereignty” refers to a set of interconnected efforts to protect peasant farmers from harms associated with agricultural trade liberalization. This entry discusses the development

of the idea of food sovereignty and outlines some of food sovereignty's component commitments. It also raises and responds to a set of critical questions about food sovereignty's role in food justice discourse.

Food Security Versus Food Sovereignty

There is an international consensus that everyone in the world has a human right to food. For example, the Universal Declaration of Human Rights (UDHR) of 1948 identifies a right to adequate food. The International Covenant on Economic, Social and Cultural Rights (ICESCR) echoed this claim in 1976. The human right to food is a rallying point for international aid and development organizations that aim to guarantee "food security." At the United Nations' 1996 World Summit on Food, participants committed themselves to this ideal, which requires that food be available, that people have access to it, and that people be able to use available and accessible foods to meet their nutritional needs (World Health Organization 2016).

Since the late-twentieth century, international organizations have argued that increased agricultural trade will promote food security. By harnessing market efficiencies – and by making capital investments in agricultural technologies in the developing world – advocates of food security have hoped to guarantee everyone's human right to food (Runge et al. 2003). However, since the early 1990s, representatives of the developing world have objected that food security discourse has been captured by efficiency-based arguments for disrupting traditional subsistence peasant farming. They object that agricultural trade liberalization harms peasant farmers.

Some of the critics of efforts to promote food security through trade liberalization have embraced a different ideal of food justice: food sovereignty (Schanbacher 2010). They demand "the right of peoples to healthy and culturally appropriate food produced through sustainable methods and their right to define their own food and agriculture systems. . . It puts the aspirations, needs and livelihoods of those who produce,

distribute and consume food at the heart of food systems and policies rather than the demands of markets and corporations" (La Vía Campesina 2011). In contrast with food security, which focuses on the availability and accessibility of food resources, food sovereignty places primary emphasis on the economic and political power of peasant farmers (Desmarais 2007; Martínez-Torres and Rosset 2010; Patel 2009).

Interconnected Goals

Food sovereignty activists embrace a large set of interconnected goals. These diverse goals oppose different harms associated with agricultural globalization.

Food sovereignty resists the destructive disruptions caused by recent dramatic shifts in global trade patterns and massive increases in demand for agricultural commodities. Trade liberalization regimes of the late-twentieth and early twenty-first centuries placed pressures on small farmers to abandon farming (because they could not compete with imports or with more efficient production methods) or to focus on producing commodity crops for exports (rather than food to feed their families and local communities). Food sovereignty aims to protect small-scale peasant farming from these disruptions and to put power in the hands of local communities to decide how (much) global capital and food imports will impact their lives (Wittman 2009).

On a related note, food sovereignty activists frequently object to the instability in food prices that trade liberalization and speculation has caused (Windfuhr and Jonsén 2005). For example, food sovereignty advocates have called for peasant farmers to receive guaranteed prices for the food they produce. Furthermore, food sovereignty activists decry the detrimental impact of declining agricultural subsidies, e.g., as a requirement of WTO membership or IMF structural adjustment loans (La Vía Campesina 1996). And food sovereignty advocates often call for new state subsidies for peasant farmers, especially for those who produce culturally appropriate foods for local consumption.

Food sovereignty advocates claim that trade liberalization has decreased the stability of the food system. On their view, the shift from subsistence farming to export-oriented agriculture makes the well-being of peasant farmers vulnerable to subtle shifts in the consumer choices or investment preferences of people in the wealthy world. Also, the shift away from peasant subsistence farming – and towards farming cash crops and increased reliance on agricultural wage labor – leaves the world’s poorest dependent on inexpensive imported foods. But these cheap food imports are sometimes nutritionally deficient, and their presence may be unreliable in economic crises.

Food sovereignty advocates also want peasant farmers to have discretion about the adoption of more efficient farming technologies, rather than have these technologies forced upon them by economic or legal necessity (Pimbert 2009). Food sovereignty also resists the ethos of agricultural efficiency because it is associated with environmental harms (e.g., pesticides, fossil fuel use) and because it relies on intellectual property regimes (e.g., seed patents) that further disempower traditional peasant farmers.

One of the boldest goals of food sovereignty movements is to promote gender justice. For example, La Vía Campesina says that “[f]ood sovereignty implies new social relations free of oppression and inequality between men and women” (La Vía Campesina 2007). This goal may seem unrelated to core food sovereignty commitments. However, valuing and protecting women’s knowledge and power in traditional food economies, and helping women to flourish in the new post-subsistence-farming food economies that economic globalization has created, will require broad social and economic efforts to promote gender equality and to end the oppression of women (Navin 2015a).

Questions About Food Sovereignty

Food sovereignty has drawn many advocates and admirers. But it has also drawn critics. And even some admirers of food sovereignty acknowledge

significant problems for the movement (Some of what follows in this section draws on Bernstein (2014)).

Food sovereignty is supposed to protect peasant agriculture from disruptions of global capitalism, but it may not be clear who is a peasant or what peasant agriculture is. This ambiguity matters. For example, if poor landless agricultural workers are peasants, then trade protectionism will not help *these* peasants, since they are paid for their labor, and since they have to purchase food with their wages, but food will be more expensive in the context of greater agricultural protectionism. However, if food sovereignty focuses instead only on the owners of small family plots who engage in subsistence farming, then it is not clear whether food sovereignty directly addresses the needs of the world’s poorest people, since landowners tend not to be a community’s worst off members. Furthermore, we should wonder whether food sovereignty speaks to the experiences of “peasants” in the developed world (Fairbairn 2012). For example, La Confédération Paysanne (LCP) represents the interests of farmers in French politics and pushes for greater subsidies for French farmers under French (and EU) agricultural policy. If these French farmers are peasants, then food sovereignty may pull in opposite directions: It would point towards agricultural subsidies for French farmers, but this would harm peasant landowning farmers in countries where cheap French imports undercut the market share of local products (Navin 2014).

Another worry about food sovereignty is whether the methods its advocates endorse will be sufficient to feed the world. Even if many people want to be subsistence peasant farmers, many more do not (or cannot). But they still need to eat. And it seems unlikely that the traditional methods that some food sovereignty activists celebrate will be able to produce enough surplus food to feed all of the people who do not engage in subsistence farming.

But even if the methods embraced by food sovereignty advocates could produce enough surplus to feed the world, it is unclear how food sovereignty advocates think surplus food ought to

be distributed. Recall that a core commitment for many advocates of food sovereignty is that food should not be sold on open markets (like others commodities) but that the distribution of food (and its price) should be controlled by farmers and agricultural communities (Rosset 2006). But how is this supposed to work? A community can set its own prices, but whether its food surplus sells depends upon the prices demanded by other agricultural producers, i.e., in a competitive market. Also, agricultural communities are likely to get higher prices (and have less waste) if they develop larger and more efficient distribution networks. But this is just to say that many of the aspects of international agricultural trade that food sovereignty criticizes may be inescapable, if food sovereignty's peasant farming communities are going to feed the world (Navin 2015b).

Finally, we may wonder about the role of the state in food sovereignty. Some food sovereignty activists advocate anarchist autarkic agricultural communities. But many of the demands that get made under the banner of food sovereignty presuppose powerful state actors, e.g., to supply agricultural subsidies or prevent global capital flows. But why do food sovereignty activists think that states will take up these causes on behalf of peasant farmers? States have been pushing hard to open their borders to agricultural trade. And why *should* states support food sovereignty? The economic losers created by increased agricultural protectionism may include many more people (including many more *poor* people) than will be included in the groups of peasant farmers who will be aided by these food sovereignty efforts (McMichael 2010).

Conclusion

Food sovereignty is a relatively new concept and it has attracted significant attention. People who are interested in ethical issues of contemporary food systems have good reason to follow the development and deployment of this concept in food justice discourse and activism.

Introduction

Farmers' organizations all over the world are very well aware that in order to build and retain a critical mass with sufficient bargaining power to

democratically influence local governments and international organizations they will have to unite by identifying common goals and setting aside their differences. After decades of local movements and struggles, farmers' organizations around the globe found in the concept of "food sovereignty" the normative framework they were long searching for. The broadness of the concept has had a remarkable success in embracing the interests of food producers and consumers from all geographic locations and development levels.

Having identified the common concept, farmers' organizations started to debate the normative implications the idea of food sovereignty brings about. The most prominent fruit of such deliberations is the declaration on "The right to produce and access land" proposed by the farmers' organization Via Campesina in Rome 1996. That year food sovereignty was defined as "the right of each nation to maintain and develop its own capacity to produce its basic foods respecting cultural and productive diversity" (Via Campesina 1996). Eliminating hunger through an authentic agrarian reform and giving farming families a larger role in the development of food trade policies are some of the main demands set in the declaration of 1996.

We will proceed by examining the different demands set in the 1996 declaration and analyze their implications for the Global South by discussing additional insights of later meetings such as the Declaration of Atitlán held in 2002 in Guatemala and the Nyéléni Forum for Food Sovereignty held in 2007 in Mali.

Food Sovereignty: A List of Demands

Demands of smallholder farmers across the world to increase food self-sufficiency go hand in hand with local advocacy for supportive food, agriculture, and trade policies. Thus, in the first declaration we can identify eleven demands (Via Campesina 1996):

1. A right to access food that is safe, nutritious, and culturally appropriate in sufficient quantity and quality to sustain a healthy life in dignity

2. A right to define agricultural and food policies (i.e., self-determination)
3. A right to practice ecologically and socially sustainable management of natural resources that allows preserving biological diversity
4. A right to prioritize local food production
5. A right to protect against dumping and “too cheap” products, including price controls and taxation to safeguard local production
6. A right to establish policies to facilitate access essential for food production to (i) productive land, (ii) credits, (iii) technology, (iv) markets, and (v) extension services
7. A right to regulate and tax speculation with food products
8. A right to be free from violence
9. A demand for more recognition for the value of agricultural labor
10. A demand for recognition of women’s role and contribution to food security
11. A demand for a long-term societal commitment to make rural infrastructure socially and ecologically appropriate (i.e., rural development)

Later deliberations (Consulta de los Pueblos Indígenas sobre el Derecho a la Alimentación 2002; Nyéléni Forum for Food Sovereignty 2007) have also specified the recognition of:

12. A right to produce food
13. A consumer’s right to choose (i) what to buy, (ii) how food is to be produced, and (iii) whom to buy from (i.e., consumer sovereignty)
14. A right to control food production in order to avoid waste and other forms of over production
15. A right to access (i) water and (ii) seeds
16. A right to prohibit the introduction of genetically modified organisms in agricultural lands and food markets

These demands concentrate around four central elements: access to the means of production, self-determination, recognition, and limiting unfair competition and intervention. These demands are not realizable if farmers themselves

do not make a commitment to recognize each other’s – including women’s – efforts and role in food production and trade.

Main Challenges to Achieve Food Sovereignty in the Global South

A central problem for the success of the food sovereignty movement is to develop a capacity to build and retain critical mass to be able to advance policies that promote common interests. This is, however, a very difficult task as there are a variety of competing movements with similar targets (Hospes 2014) and well-established powerful private interests groups who benefit enormously if farmer organizations remain fragmented. Among the groups fighting for a similar cause we can find people from United Nations organizations who try to secure access to food using the human rights language, especially the right to food discourse (De Schutter 2011). Another group prefers recalling principles of commutative justice by fighting for decent remuneration and work conditions relying on fair trade principles (Raynolds 2014). A further group also works with the justice discourse but argues that food justice needs to go beyond focusing on fair transactions and include environmental sustainability, democratic decision-making, safe work environments, and access to healthy food (Food Ethics Council 2010). While the different groups tend to agree on the most important goals – accessibility and availability of food, decent farm work conditions, and ecological sustainability – they disagree on the strategic discourse to achieve these aims. We should not underestimate the power major multinational corporations and political parties with neoliberal trade policies have to influence the discourse, and especially in the Global South, to assert licit and illicit pressure on farmers’ organizations. Here the old Roman saying – *divide et impera* – best describes the opportunity for corporations and neoliberal governments, and the vulnerability of farmers’ organizations.

The food sovereignty movement in the Global South has the added difficulty that farmers count an extremely large number of people with varying

priorities and opportunities. These farmers and their families face huge collective action problems as a group and have together and individually little disposable income to organize their interests. Multinational corporations who want to introduce their products in local markets and governments seeking to attract foreign investments have a much more structured agenda and have much more income at their disposal to organize campaigns to change public opinion to their advantage (Ziegler 2011). States as sovereigns have also the authority to sign large-scale long-term land lease agreements and dictate agricultural policy. In comparison, individual farmers have repeatedly the temptation to deviate their actions from collective interests, as they often can improve their odds or avoid risks by free riding from collective efforts. The need for disposable income increases this temptation, as farmers, like anyone else, are embedded in a social context where they face social pressures and demands as diverse as school materials for kids and fashionable clothing for the youth.

Farmers in the Global South also recognize that they have a major problem with inadequate training (Nyéléni Forum for Food Sovereignty 2007). Capacity building is needed to improve the organization, advocacy, and deliberation capabilities of farmers' organizations, to build new food retail channels, to recover traditional farming techniques, and to learn and improve agroecological farming methods. There is also a strong demand that information on agricultural and food policy, technological risks, and trade agreements be made transparent, precise, and understandable for a wider audience (Consulta de los Pueblos Indígenas sobre el Derecho a la Alimentación 2002). Implicit is the demand that documents should not contain a massive amount of redundant details that makes careful screening prohibitively expensive for smaller organizations, as we can observe in several ongoing trade agreement negotiations.

There is still a major research effort needed to meet the demands for ecological sustainability, even more, if we take into consideration the rapid migration to urban areas within Global South. Intensification of ecological processes in

agriculture is to be based on achieving local yield potentials, enhancing soil quality parameters, and integrate precision agriculture schemes that value both technological advances and farmer knowledge (Tiftonell and Giller 2013). Yield potential can be reached through proper diagnostics of farming system issues and redesign of the systems taking into account locally available biological diversity as well as farming families' aspirations. Soil quality needs adequate land management that prevents topsoil erosion, promoting physical, chemical, and biological parameters to express fully. Whether with use of GPS-guided tractors or farmers' knowledge of the landscape, by engaging into a precise form of agriculture it is possible to assess and remedy site-specific situations that undermine yield and soil potentials.

Important to note is that shifts towards food sovereignty and ecological sustainability will clash with feasibility constraints unless major efforts to adapt agriculture to growing urbanization are made (Bernstein 2014). There are, however, a number of current initiatives and projects to grow more food in cities, such as aquaponics (a combination of aquaculture and hydroponics), roof gardens, vertical farms, allotment (community) gardens, and towers for animal production. Cuba, for example, has shown a remarkable success in instituting ecological urban agriculture by transforming underused lots in community gardens (Altieri et al. 1999). Despite technological advances, ecological sustainability still has the constraint that societies need obliges us to identify and respect the balances we have to maintain with nature and see how to align these with the dynamic needs of a continuously changing society. Food sovereignty therefore not only requires scientific and technological advances but also social and ethical innovations.

Aside from collective action problems, in many societies around the globe, there is still a huge deficit and lack of will to address issues of gender inequality (Agarwal 2014). The various declarations of food sovereignty acknowledge the essential role women play in food production and preparation, and demand recognition for their effort. There is a strong need to abolish

discriminatory laws for divorce and inheritances, especially as these laws jeopardize access to land for women (Nyéléni Forum for Food Sovereignty 2007). It will be a major challenge to ensure proper recognition and gender equality in societies characterized for embracing patriarchal principles, as it will require that people let go from some deeply anchored traditions.

There is an urgent need to address the health challenges current food systems are having on people in both the Global North and Global South. Especially poor people in transition economies have acquired eating habits that are detrimental to their health. Fresh fruits and vegetables are in urban areas often more expensive than food rich in saturated fats, salt, and sugars. As children tend to acquire the same eating habits as their parents, poor eating habits are passed on from one generation to the other, and so also the vulnerabilities and financial burdens of non-communicable diseases malnutrition leads to. Society ends up paying triple for such bad food policies. People pay for wrongly set subsidies that encourage the production of staple foods, for the advertisement costs of processed food, and for the public health costs of malnutrition (De Schutter 2011). Hunger and diets that do not offer the minimum doses of vitamins and minerals are still endemic in the poorest regions of the world. Here we should note that it is vital to ensure proper nutrition between conception and the end of the second birth year, as malnutrition may lead to permanent damages in the child's development (Ziegler 2011).

A problem for the food sovereignty movement is that local food is not necessarily healthy and consumers do not make continuously healthy food choices. As much autonomy and consumption of local food may be involved in a gaucho's preference for free-range Patagonian meat, a Mexican's craving for *tacos dorados*, or an Antillean's appetite for a deep-fried plantain dish; if these food choices become habitual, someone will have to assume the tasks of informing consumers that these dishes form an unhealthy diet. Similarly, traditional dishes that are a constitutive element of a people's heritage are not always healthy either. Supplying the ingredients for such dishes

for current population levels may also not be ecologically and socially sustainable anymore. The sustainability demands set forth in food sovereignty may request that people adapt their diets by including food products that are foreign but can be produced with less environmental impact and avoid traditional dishes that demand products that cannot be grown or catch in sufficient numbers in a sustainable manner. In many regions of the world this means reducing meat consumption and eating more frequently a variety of pulses (legumes). The simplicity of this rough statement stands deeply at odds with current shifts within the food system. Over the last decades the food chain has been changing from a supply system to a demand system (Korthals 2001). Food sovereignty and consumer sovereignty can only coexist if consumers learn to make sustainable food choices and prevent food waste by absorbing eventual seasonal oversupplies.

Alarming from a social and environmental perspective is the extensiveness of land areas that are untouched by a rule of law that the least faintly adheres to human rights principles. Such areas often employ a massive number of people of all ages who work as slaves or in conditions similar to slavery, adding to millions worldwide. Drug cartels and sympathizing local governments have caused massive displacements of people who are usually driven to poverty as they lose their land and often suffered physical and psychological damages that impede them to live normal lives. The unregulated cultivation of opium poppies, cannabis, and coca bushes in a number of countries of the Global South – in particular Afghanistan, Myanmar, Mexico, and Peru – is becoming so extensive that it causes major disruptions in food security and the ability for governments to regulate the use of environmentally sound agricultural inputs. To gather an idea of the magnitude of such plantations, we can refer to Afghanistan's cultivation of 220,000 ha of opium poppy; Peru cultivated illicitly about 49,000 ha of coca bush, and Colombia farmed roughly the same surface (United Nations Office for Drugs and Crime 2015). Mexico and Afghanistan reported massive cultivation of multiple illicit crops (ibid). Large-scale police and military action is devoted to

continuously destroy such plantations. To recover losses, drug cartels continuously clear new land areas, provoking anew the displacement of people and the destruction of nature.

Access to land for food production is also constrained affected by individual farming choices and changes in profession of farmers' children. Many smallholders are now farming cash crops, such as cotton, and encourage their children to opt for other professions (Agarwal 2014). Rural populations age as the youth move to apparently more lucrative endeavors such as mining or try their odds in the big cities. A major challenge for food sovereignty will be to stimulate a new generation of young people to choose to work the land. As a measure to achieve this goal, farm work quality needs to be significantly improved by increasing autonomy, encouraging experimentation, and building better farmers' knowledge exchange networks (Timmermann and Félix 2015).

Criticisms on the concept of food sovereignty concentrate on issues of feasibility in a world that has accepted free trade principles and a lack of consensus and specification on the underlying concept of sovereignty (Hospes 2014). Farmers around the globe still have to agree on the concept of sovereignty. At which level should decisions be made? State, region, township, or peoples? This is a very important issue in the Global South, as borderlines of a large number of countries were drawn by colonial powers without regard of ethnic groups and geographic terrains thus making it difficult to draw adequate common policies. At the moment there seems to be a consensus on people's food sovereignty (Agarwal 2014). We will have to wait for the future to see how these demands can be implemented in and across local governments.

Future Outlook

The major future challenge for food sovereignty in the Global South is extreme inequality. People who suffer deprivation are much more vulnerable to be exploited by those who have more financial resources and power. The poor are more likely to

lose their land and to offer their labor for miserable wages. Governments who desperately need foreign investment are more willing to sign large-scale land leases. Such deals often result in a shift of agricultural production from food to biofuels (Ziegler 2011). Extreme inequality also makes it easier for powerful groups to illicitly influence political decision-making for their own advantage at the cost of the poor thus weakening states. And states that are or become weak are much more vulnerable to military coups and less able to control drug cartels.

An additional problem for future food production is climate change, which will have its harshest effects in countries of the Global South. These countries face already the highest hunger burden and have the smallest budgets to adapt agriculture to upcoming environmental changes.

These problems will put an enormous pressure on the food system and will raise a strong social demand to make the most efficient use of land. As land is a limited resource, farmers will face an increased difficulty in sovereignly deciding on agricultural practices.

Exports; Food safety regulations; Global food system; International trade; Poverty alleviation; Sanitary and phytosanitary standards; Technical regulations

Introduction

Food safety standards are a part of technical regulations categorized as sanitary and phytosanitary (SPS) regulations that principally aim to ensure food safety of consumers and plant and animal health (Josling et al. 2004). Due to their potential adverse effect on international trade, however, the growing attention has recently been paid to food safety standards and other technical regulations as trade has been substantially liberalized through tariff reduction. Inherent difficulty in reaching a desirable policy solution regarding food safety standards lies in the fact that there are various losses and benefits associated with their application. Because food safety standards are designed to achieve the level of safety that is acceptable to the society, reduction or elimination of food safety standards to advance trade liberalization could conflict with this social objective. On the other hand, producers, particularly those in developing countries, may suffer from the additional production costs due to their compliance with food safety standards that are normally more stringent in developed country markets.

A quantitative assessment of the losses and benefits associated with various food safety standards would assist policy makers to determine appropriate levels of regulation. This justifies coordinated effort between social and natural science because food safety standards, economic outcomes, and consumer's safety are closely interconnected. Effort to synthesize the findings in the related academic fields such as economics, and food and biological science, would considerably benefit policy decisions.

This entry attempts to provide an integrated picture in regard to the economic and scientific aspects of food safety standards by drawing on studies on health risks of regulated chemical and microbiological elements and the impact of food safety standards on trade and producer's performance.

The subsequent section provides definitions and background for food safety standards. Section “[The Economic Analyses of Food Safety Standards on International Trade](#)” discusses the economic impact of food safety standards on trade and producer's performance. Section “[Health Consequences of](#)

Food Safety Standards and Consumer's Perception" discusses the impact of food safety standards (or food safety risks) on human health and the consumer's perception of foods safety risks. Section **"Summary"** summarizes the discussion and provides policy recommendations.

Food Safety Standards and Their Role

Food safety generally refers to the contents of various chemical and microbiological elements in food (Burlingame and Pineiro 2007). Food safety standards may be categorized into product standards that specify set of safety characteristics and their bounds of the food in the final form and process standards that define how the food should be produced. Product standards are applied typically in the form of numerical standards such as maximum residue limits. Process standards are sometimes more efficient than product standards in reducing food safety risks as appropriate production process can reduce incidence of contamination to microbial elements (Josling et al. 2004). Food safety standards also correct the information asymmetries about product attributes associated with food safety between producers and consumers as consumers are often not fully informed about product attributes.

The World Trade Organization (WTO) Agreements on SPS and technical barriers to trade (TBT) established in 1995 make sure that the member countries set technical regulations in line with the international standards, thereby preventing the technical regulations of member countries from constituting nontariff barriers (NTB) to trade. Major international standard setting bodies include the joint Food and Agriculture Organization of the United Nations (FAO)/World Health Organization (WHO) Codex Alimentarius Commission (Codex) for food safety and plant health and the World Organization for Animal Health (OIE) for food safety and animal health. The SPS and TBT agreements recognize the importance of food safety standards as effective regulatory instruments to protect food-related safety, but require the regulating countries to submit scientific evidence to justify the regulations if they are more stringent than the international standards where exist.

The Economic Analyses of Food Safety Standards on International Trade

The Country-Level Evidence of the Effect of Food Safety Standards

Trade impact of food safety standards is one of the essential pieces of information for policy decisions. Since the stringency of food safety standards tends to be positively correlated with the stage of economic development as shown in Wilson and Otsuki (2003), developing countries tend to have difficulties in exporting to developed countries. Moreover, high dependency of developing country's income and employment on food production implies the high potential loss in food export from developing countries when they are required to comply with the level of food safety standards of developed countries. If trade loss is small, then stringent standards may be permitted. If trade loss is large enough, however, the levels of standards should be set with a particular care.

Otsuki et al. (2001a) analyzed the effect of the EU aflatoxin standards on imports of groundnuts from 15 major groundnut-exporting African countries. The aim of the study was to investigate the impact of the European Union's harmonization of maximum aflatoxin limit in imported foodstuffs in 2002. The limit was set at a very stringent level compared to the Codex's international standard, and it triggered serious concerns among exporters of food products. For example, a representative of the Gambia claimed that "the proposed standard would effectively restrict entry of the Gambia's groundnuts and essentially the groundnuts from producer countries in the European world to the EU" (World Trade Organization 1998). Otsuki et al. (2001a) aimed to examine whether a tightened food safety standard really reduced groundnut export from developing countries. Otsuki et al. (2001b) found the trade-restricting effect holds for an expanded set of product – cereals, dried fruits, and nuts – in the same set of importing and exporting countries.

Xiong and Beghin (2012) reexamined the analysis of Otsuki et al. (2001a) by a theory-oriented gravity model. This study reported an insignificant net effect of EU aflatoxin standards on African groundnut exports. Importantly, their model

allowed to decompose the supply and demand effects of standards, thereby accounting for the result as an interaction of these two effects; a demand-enhancing and trade-cost effects of standards may have been cancelled. Standards may attract demand by enhancing transmission of information on product characteristics and improving product safety and quality whereas constraining export supply by increasing compliance costs. Xiong and Beghin (2013) also reported similar results regarding the counteracting demand and supply effects of food safety standards for animal and plant products as a whole.

Wilson et al. (2003) found a negative effect of residue limit standards on tetracycline, as an antibiotic veterinary drug, on beef exports from the major beef-exporting countries. Wilson and Otsuki (2003) also found a negative effect of residue limit standards on chlorpyrifos, as a pesticide, on banana exports from the major banana-exporting countries. Anders and Caswell (2009) studied the impact of US HACCP standards on food trade from the top 37 suppliers of seafood using the standard gravity model. They found HACCP impeded exports from developing country exporters, but trade promoting for developed countries.

Disdier et al. (2008) examined the effect of TBT and SPS on agricultural and food imports from the OECD countries. They also compared the effect of a 1% increase in the tariff equivalent of SPS/TBT on trade value between the cases of developing and OECD countries as exporters and found that tightening of SPS/TBT could lead to a moderate decrease (0.14%) in trade.

Drogué and DeMaria (2012) studied the impact of pesticide residue limits of importing countries on apple and pear exports worldwide. They found that the more similar are the regulations of importing and exporting countries, the greater the trade flows. Chile, South Africa, and Brazil (although insignificant) follow this pattern (trade promoting). Winchester et al. (2012) estimated the impact of pesticide residue standards on all plant products and found that the heterogeneity of the regulations can deter the trade of both developing and developed countries. Winchester

et al. (2012) analyze the effect of bilaterally differing food safety standards on trade of all plant products.

The Microlevel Evidence of the Impact of Food Safety Standards

Capacity constraints that producers face in complying with food safety standards, typically in developed countries, may be significant as several case studies have descriptively demonstrated (see, e.g., Wilson and Abiola (2003) and Aloui and Kenny (2005)). Among quantitative analyses, Ragasa et al. (2011) investigated the effect of firm's compliance to food safety regulations using the survey data from seafood production firms in the Philippines. They estimated incrimination of production cost due to food safety standards is over 100%. Maertens and Swinnen (2009) and Maertens et al. (2011) demonstrated that stringent food safety standards on fresh and processed fruits and vegetable in Senegal can rather increase developing country export to developed countries through increased employment of rural poor farmers in the export sector aiming at high-standard market.

The World Bank's TBT Survey Database of 17 developing countries on the firms' response to various technical barriers in their domestic and export markets revealed that for approximately 70% of the surveyed developing country firms, the cost of testing and certification prevented them from exporting to major developed country markets. The firms tried to comply with the technical requirements by expanding their plant or equipment, redesigning products, and hiring labor for production/testing. The actual total compliance cost is, on average, 4.4% of the firm's production cost – not prohibitively high, but it still presses down the firm's export. Maskus et al. (2013) quantified the amount of fixed costs of compliance with various technical regulations and the degree of additional firm-level variable costs due to the technical regulations using the TBT Database. Chen et al. (2008) estimated firm-level export function of intensive and extensive margins using the same database. They identified the factors to promote the amount of export in a firm's total sales (intensive margin) and the

number of export markets and products to be exported (extensive margin). Compliance with quality standards is found to increase the export amount as well as the number of export markets and products to be exported. On the contrary, standard certification procedures are found to reduce the number of export markets and products to be exported.

Health Consequences of Food Safety Standards and Consumer's Perception

Hazards and Health Relationship

Scientific research on relationships between an intake of regulated food safety hazards and health consequences is inconclusive in many cases. Based on scientific research, Etzel (2006) described potential effects of mycotoxins on child health, and they vary from vomiting to severe disease such as liver cancer. Sherif et al. (2009) provided a comprehensive survey on the relationship between a mycotoxins intake and child health, particularly in developing countries. They synthesized the major potential adverse health effect as poor growth and development and suppressed immune as well as cancer. However, they noted that risk assessment is complicated and is constrained by lack of data.

Otsuki et al. (2001b) compared the economic gains and loss of human lives from relaxing aflatoxin standards in the EU, based on JECFA's analysis of potential health effect of aflatoxin for two hypothetical levels (10 parts per billion (ppb) and 20 ppb) (JECFA estimated that implementing a 10 ppb total aflatoxin standard leads to a risk of 39 cancer deaths per year per billion people, with an uncertainty range between 7 and 164 people. In comparison, a 20 ppb standard yields a risk of 41 cancers per year per billion people with an uncertainty range between 8 and 173 cancer deaths. This implies that reducing the standard from 20 to 10 ppb in countries where percentage of carriers of hepatitis B1 is around 1% (e.g., members of the European community) would result in a drop in the population risk of approximately two cancer deaths a year per billion people).

Otsuki et al. (2001b) calculated the cancer death risks associated with different regulatory scenarios they examined – the new harmonized EU standard (2 ppb) and a Codex standard (9 ppb) in terms of an Aflatoxin B1 equivalent. Approximately 0.2 cancer deaths will be saved each year by tightening total aflatoxin standards by 1 ppb, if a linear relationship is assumed between cancer death risk and aflatoxin intake. Assuming that 60% of all aflatoxins are in fact Aflatoxin B1, by adopting the average of the lower (50 ppb) and upper. For groundnuts, other nuts, dried and preserved fruits, and cereals for direct consumption, the difference between the codx and the new EU standards is 7 ppb. Provided that these foods fully account for the aflatoxin intake in the JECFA's scenario, this implies that the EU standard will result in 2.3 less cancer deaths per year than when the baseline level is taken.

This finding does not necessarily weaken the importance of food safety standards, but rather stresses the importance of consideration of both economic gains and effects on human health in setting standards. It also motivates the need for interdisciplinary research that directly combines economic and scientific analysis associated with a specific policy. It is also important that scientific research should update their findings with a more modern and advanced assessment methodologies as well as an increased availability of data to be used for the assessment.

Consumer's Perception of Food Safety Risks

Consumers play an important role in setting food safety standards because consumer's demand for safety would be reflected in actual regulations. Consumer's demand for food safety may be affected by publicly available information on the causality as well as subjective perception of food safety risks. Consumer's demand for food safety does not necessarily reflect the fact that scientific risk assessment has found because of the presence of subjective perception of risks. This subjective perception of risks also involves unknown future risks. Risk aversion of consumers against unknown future risks leads to precautionarity. Therefore, the targeted level of food safety will depend on whether the level should be based

purely on the scientific facts or on consumer's perception of risks. This deviation tends to be greater when consumers are not precisely informed of the scientific facts. The health effect of food safety hazards may vary across individuals, locality, and countries (Sherif et al. 2009). Reaction to food safety hazards also may be heterogeneous.

Hypothetical valuation of consumer's willingness to pay for food quality and safety tends to yield a large estimate of price premium due to the so-called hypothetical bias (Caswell and Joseph 2007). This consumer's tendency may at least partly account for the demand for country-level food safety regulations that are far more stringent than the international standards. Furthermore, lack of information on food safety may reduce credibility of safety of imported products. Information on food quality and safety characteristics also plays an important role in affecting consumer's behavior (Caswell and Joseph 2007). In order to avoid excessive demand for food safety, it would be important to provide information on both product characteristics and their effects on human health.

Summary

The studies on the relationship between food safety standards and food trade generally find trade-off between them. However, some of them also find a demand-enhancing effect of tightened standards, implying a potential payoff to the suppliers from complying with the standards. The microlevel studies also suggest the existence of both the trade-cost effects and the demand-enhancing effects. Therefore, it is important to promote compliance of the suppliers to a certain level of food safety standards while avoiding to impose unnecessarily stringent standards at the same time. Thus, it is important that the international standards are carefully set at the appropriate level which ensures a sufficient level of human, animal, and plant health without causing a significant loss of international trade and profits of suppliers. Such standards should be revised periodically reflecting an improved economic and scientific research. Also, it is important for

international standards to cover a broader set of products and food safety hazards.

It is also important to provide consumers with information on food safety and quality characteristics in order for them to make an informed decision by providing information on product characteristics through labeling and information on the scientific fact on the health effects of food safety hazards. Thus, we can avoid departure of the standards based on risk assessment from those demanded by consumers, thereby achieving an efficient function of agricultural and food market.

Regionalism; Tourism

Introduction

In the context of culinary tourism, food is used as a vehicle on which to embark on a culinary and historical journey. Such tours or journeys are often thematically focused around culture, history, religion and/or socioeconomic class within a small geographic space. Thus, food tours offer a means of exploring the nexus of history, culture, and food as rhetorically constructed and performed in the context of particular environments. Food tours, or culinary tourism, are not without their inherent ethical considerations such as cultural appropriation, cultural slumming, commodification, and exoticizing the Other.

Significance of Culinary Tourism

Also known as gastronomic tourism, culinary tourism, according to the World Food Travel Association, is the “pursuit of unique and memorable food and drink experiences.” The tourist focused on a culinary experience may select their travel destination based on the local cuisine or they make food and drink the focus of their travel activities, in the same way that one may choose to visit art museums or national monuments.

Culinary tourism is often classified as a subset of cultural tourism in the sense food is product of culture. This includes cultures based on religion, heritage, national boundaries, socioeconomic class, and ethnicity. Culinary tourism differs from agritourism which is considered a subset of rural tourism. They are, of course, inextricably linked, as cuisine is the byproduct of agriculture. While once regarded as an elite form of travel focused on gourmet food, culinary tourism today is vast in scope and includes participating in bacon cook-offs, beer tasting, and BBQ oyster festivals.

The significance of culinary tourism is both symbolic and economic. Long explains that “. . . food is a resource for enacting and constructing group identity as well as for symbolic communication and that tourism has shaped the ways in which that resource is used” (2004). In *The Archeology of Food and Identity*, Dietler describes food as

“embodied material culture” in which cultural identities are communicated (2007).

Culinary tourism is also big business: “tourism expenditures on food services in the USA topped \$201 billion, nearly a quarter of all travel income” (Liu et al. 2013). Moreover, “food and beverage are an increasingly significant motivator for travel, as 75% of leisure travelers have been motivated to visit a destination because of a culinary activity” (Wolf 2016). The popularity of culinary tourism is a national and global phenomenon. The American Culinary Traveler (2013), reports an increase from 40% to 51% between 2006 and 2013 of US leisure travelers who seek unique dining experiences on their travels. According to the specialized agency of the United Nations, the World Tourism Organization’s (UNWTO), global report on food tourism, over a third of tourist spending is devoted to food. The World Tourism Organization also reports that “88.2% of survey respondents consider gastronomy a defining element of the brand image of travel destinations. Only 11.8% of respondents considered gastronomy to play a minor role.” The same report indicated that “over a third of tourist spending is devoted to food” (2012).

The history of documenting the upward popularity and trend of culinary tourism goes back to 2001. Executive Director and Founder of World Food Travel Association (formerly known as the International Culinary Tourism Association), Erik Wolf, presented a white paper about culinary tourism. The paper evolved into the book *Culinary Tourism: The Hidden Harvest* that documented the growing interest in food and wine tourism and how requests for culinary tours could drive local businesses and restaurateurs to meet the growing demand.

The Rise in Food Tourism

There are several contributing factors to the current rise in culinary tourism. Popular culture, technology, and social media are ingredients for promoting food consumption and “food talk,” what Priscilla Parkhurst Ferguson calls *Word of Mouth*. As food and cooking are increasingly the topics of books, television shows, Web sites,

food and travel blogs, and documentary films, food and cooking have moved from being tools of survival to forms of leisure activity.

Concurrent with the increased presence of “food” as a subject, is the increased use of social media sites and apps. At present, social media sites have become a predominant means for communicating class and cultural identity. While there is a long history of using consumer goods to convey one’s social standing, such as cars, luxury vacations, and designer clothes, food and eating have become the latest status commodities. By sharing what we are eating and drinking and where we are dining, we can communicate our social, economic, cultural, religious, and political status across the globe. As such, food is no longer stylized just for the plate, but to be posted, tweeted, pinned, and shared with our friends and followers. Traveling to new places to sample new foods and restaurants are another form of conveying one’s culinary social status and sense of adventure. Eating insects in a foreign land has become akin to planning a vacation to ski the toughest mountain or swim with dolphins. According to McGuire, “When people go on vacation, you will be able to spot the food-conscious traveler by the ratio of exotic food photographs there are in their albums compared to photographs of sites and people. People treat their consumption of foreign food in much the same way that they would their visitation of a famous architectural structure or painting. It shows their openness to learning, their desire to see all the world has to offer, and the scope of their imagination” (2015).

Describing the relationship between social media and food tourism, McGuire claims that social media is driving interest in food. She states that “a cursory search of the #food and #foodporn tags on Instagram will reveal millions of shots (168,422,776 posts and 76,245,234 posts, respectively) of meals, beverages, ingredients, and food makers. It’s no secret that people are obsessed with food photography, due to the prominence of foodie culture in mainstream media” (2016).

Demographic shifts also play a role in the recent rise of culinary tourism. The Pew Research Center, in its report, “A Portrait of Generation

Next,” paints a picture of millennials who are driven by freedom of choice and lifestyle and tend to be health-conscious and food-conscious. This generation is likely to be adventurous, seek new experiences, and explore options to communicate via social media (2007). Mixed with these values are the matters of economic privilege and opportunities. The “hip” side of the Food Movement has been criticized for privileging those who can shop at health food stores, buy gourmet food products, drink craft beer, eat at niche restaurants, and take a food-themed vacation. On the other hand, millennials reportedly are confident and connected; they can, and do, critique food practices associated both with the “establishment” and with “alternative” cultures. Today, for example, there is more awareness of the relationship between socio economic privilege and food choices, and food justice issues are becoming more main stream.

Types of Food Tourism

Two of the primary reasons for sampling the food, drinks, and food culture of different communities, regions, and countries are to discover new flavors, ingredients, and cooking techniques and to participate in the local community. UNWTO defines gastronomic tourists as people who “take part in the new trends of cultural consumption. They are travelers seeking the authenticity of the places they visit through food. They are concerned about the origin of products. They recognize the value of gastronomy as a means of socializing, as a space for sharing life with others, for exchanging experiences” (2012). Depending on one’s interest, budget, and destination, there numerous ways to be a culinary tourist such as taking cooking classes, attending food festivals and events, and participating in food tours.

Attending Cooking Classes or a Culinary Institute

On type of culinary travel is attending a culinary institute. Culinary institutes and chef training

schools often offer programs and events for food lovers who want to learn about the local restaurant industry, emerging food trends, food preparation techniques, or recipes for regional dishes. Italy, Spain, and other countries in the Mediterranean, for example, offer farmhouse cooking vacations, where visitors can live in a farmhouse or villa for an extended period of time and learn about local and regional cuisine. The TV chef Andrew Zimmern says, “a cooking school vacation can be an immersive experience that teaches you all about a culture – and how to cook its cuisine. You can come back and be a very accomplished performer in your own kitchen” (Bleiberg 2014).

Some popular institutes include The Culinary Institute of America, the United States’ premier culinary college. With locations in St. Helena, CA, Hyde Park, NY, and San Antonio TX, the CIA offers culinary two-, three-, four-, and five-day culinary boot camps. Boot camps are offered across a range of topics such as farm to table cooking, food and wine pairing, BBQ and grilling techniques, Asian cuisine, pastry making, artisanal pizza and pasta, and flavors of Texas. With locations in New York City’s Flatiron and downtown districts, Chicago, and Boston, Eataly offers stand-alone cooking classes and culinary events in all things Italian. Here, one can learn the art of pasta, pizza making, and sausage preparation. Those looking for international experiences may be interested in Immerse Through tour, which is based on the “concept of cultural immersion through food” (<http://www.immersthrough.com>). Focusing in the East, Immerse Through offers food tours in Burma, Chaing Mai, Iran, and Georgia.

Artisan Food, Beverage Fairs, and Food Festivals

Throughout history, people have travelled to attend music festivals, plays, and museum openings. Travel for the arts has now expanded to traveling for food and drink. While making a trip to the “wine country” had long been a popular food and beverage journey, food and drink travel now includes attending a celebrity chef competition, sampling local food trucks, making a

pilgrimage to a destination restaurant, or attending a food festival. Like culinary tourism in general, food festivals are increasingly popular.

Some festivals focus on a particular food or drink native to the region. The Maine Lobster Festival, for example, began as a small community idea in 1947 and draws a crowd of 30,000 every year. Known as the “Oyster Capital of California”, Humboldt County, CA draws 10,000 people every June for the Humboldt Bay Oyster Fest. Portland, OR hosts 35 food-themed events throughout the year such as Macaroon Day, VegFest, Tualatin Crawfish Fest and the Elephant Garlic Fest. Famous for their alcoholic beverages, Portland is also home to 12 spirited festivals such as the Bourbon and Bacon Fest, Holiday Ale tasting, Sake Fest, and WhiskeyTown USA, which features more than 200 varieties of whiskey over 3 days.

Others food festivals are more general and allow guests to sample a range of new foods and flavors at one large event. The Melbourne Food and Wine Festival, for example, draws a crowd of 250,000 each year. The San Francisco Street Food Festival, which began in the Mission District, has outgrown its traditional home and in 2016 had to move to a much larger space at Pier 70. The popularity also forced organizers to expand from one to two days. Over 50,000 people attend this annual event. Started in 1980 with a “build it, they will come” attitude, Taste of Chicago is one of the largest tourist attractions in Illinois and the largest food festival in the USA. Over one million people attended in 2016.

Food Tours

Also a popular tourist activity, culinary tours and specialty dining experiences offer travelers the opportunity to visit various restaurants, cafes and bistros, meet with chefs, and take part in food seminars or special events. These sorts of tours are generally run by tour companies in major cities and offer a mix of walking and driving tours to sample foods from particular ethnic neighborhoods within the city. In NYC, for example, one can participate in a pizza tour of the

Lower East Side, a taste of Chinatown, or sample the best of Brooklyn. Visitors to New Orleans, LA can participate in a Food Tour of the French Quarter or a Cocktail History walking tour. While in Texas, one can taste in the Cellar Rat Wine Tour, ride the 290 Wine Shuttle, or the Texas Beer Bus.

Ethical Considerations of Food Tourism

As food and culture are inextricably linked, culinary tourism is not without ethical implications. Practices such as culinary slumming, commodification of culture, cultural appropriation, and exoticizing the Other can be found in many current and popular forms of culinary tourism.

Culinary Slumming

According to Kelly, “culinary slumming refers to the unreflective enjoyment of adventurous cuisine that is by-and-large the product of poverty and marginalization” (2015). This is an extension of Eldridge “Cleaver’s incitement of soul food as a practice of middle-class black slumming” (Witt 2004). The appeal of culinary slumming is to flavor “the dull dish that is mainstream white culture” (Hooks 1992). The culinary slummer is not seeking exclusive five-star dining experiences, but seeks instead the rare, the bizarre, the forbidden, and the exotic – the most Other food experience. These experiences are often the result of histories of poverty and marginalization that forced cultures and peoples to adapt and survive off the meager rations or ingredients they were able to obtain.

Culinary slumming, as a hobby and tourist activity has become increasingly popular with the rise in food television, such as *Bizarre Foods with Andrew Zimmerman*. (Kelly 2015). Yet, this travel objective is not without its ethical dilemmas as it “not only overlooks the economic and cultural factors that have shaped cuisines of necessity, but glorify[s] those cuisines as the proud and exotics traditions of simple but indigenous people who live off the land without pretense” (Kelly 2015).

Although culinary slumming is largely considered a modern phenomenon because of the number of people interested and economically privileged to engage in this tourist activity, an early form of it can be traced to 1889. According to the legend, Queen Margherita tired of French cuisine on a visit to Naples, wanted to try authentic Italian *lazzaroni* (poor) food (Helstosky 2008). At that time, the *lazzaroni*, ate a lot of baked dough topped with almost rotten tomatoes – the early pizzas – in the streets of Naples. In anticipation of their arrival, Pizzaiolo Rafaele Esposito of Pizzeria Brandi prepared multiple pizzas for the king and queen, one of which was made with mozzarella, tomatoes, and basil to symbolize the red, white, and green of the Italian flag (Berg 2015). Queen Margherita declared this her favorite pizza, and it has since been referred to as pizza Margherita. Queen Margherita was one of many aristocrats to help move pizza out of the streets and into the mainstream, and this fascination with the *lazzarone* and their pizza thus illustrates an early form of culinary slumming.

Cultural Appropriation or Cultural Celebration

There can be a fine line between celebrating cultural traditions and appropriating them for one’s own purpose. The multiple uses of and perspectives on Native American fry bread, illustrate this balance. In 1854, the United States government forced indigenous peoples to move from Arizona to New Mexico during the “Long March” (a series of 53 forced marches of 9000 people across 300 miles from 1864 to 1886). When Indians arrived in New Mexico, they realized that the land could not support their traditional diet of beans and vegetables. In order to prevent starvation, the US government supplied them with canned food and staples such as flour, sugar, and oil – the makings of fry bread.

The deep-fried bread has particular significance and is of great pride to the Navajo nation, the second largest federally recognized tribe, as they are the ones who first developed the recipe. As such, it is often served at native celebrations.

However, while fry bread represents the historical struggles and perseverance of indigenous peoples, it is also at the center of contemporary health concerns. According to the US Department of Agriculture, one slice of fry bread (the size of a large paper plate) has 700 calories and 25 grams of fat. The combination of ingredients and the centrality of the food in powwows and celebrations have caused many to blame fry bread for the high rates of obesity and diabetes in indigenous peoples (Miller 2008). Suzan Shown Harjo (2005), Indian writer and activist, wrote, "I promise to give up fat 'Indian' food this year and to urge others to do the same. Target number one: the ubiquitous fry bread – the junk food that's supposed to be traditional, but isn't, and makes for fat, fatter, and fattest Indians." She explains that while "fry bread is emblematic of the long trails from home and freedom to confinement and rations. It's the connecting dot between healthy children and obesity, hypertension, diabetes, dialysis, blindness, amputations, and slow death. If fry bread were a movie, it would be hard-core porn. No redeeming qualities. Zero nutrition." This attack on the food and its cultural significance caused a backlash within Native communities. To further complicate the symbolic meaning of fry bread, many non-native communities are capitalizing on fry bread's popularity and using it to raise money at school fundraisers. This commodification of food from another culture is criticized for profiting on the struggles of indigenous peoples.

Food, Foodways, and Culture as the Exotic Other

On some food tours, food is used solely as a thematic feature, versus as a means to explore, learn, and understand another culture. When this occurs, food is constructed as the Other which "tends to be thought of as cuisines representing ethnicity or exotic cultures vastly different from one's own" (Long 2010). The act of eating (the Other), not cultural, culinary knowledge becomes the primary goal. When eating is the primary goal, the role of food is reduced to its most primary function – something to be consumed. When

tourists are not provided explicit and detailed connections between foodways and peoples, their only choice of interaction is consumption (versus listening, learning, or understanding).

The implications food as Other versus food as a means of education are twofold. When the goal of culinary tourism is to tell the history of peoples through experiential learning, foodways, and cultures are steeped in context and food is expressive of history, religion, socioeconomic standing, and geography. This relationship between food and people may foster cultural appreciation and an understanding of the impacts of multiple identities on foodways.

In contrast, when the primary goal is to see food as an exotic product to be consumed, foodways and cultures become devoid of context. Such lack of contextual knowledge can present and enhance food's image and representation, and the people who traditionally make and consume it, as Other. According to Elliott, "Representations of the Other through food and its packaging have great symbolic potency, and this 'labeling' of foreignness proves significant precisely because it seems so innocuous" (2008). Not only does the lack of context reduce or obliterate the food's cultural significance, it further reduces the food to simply a product. The product nature of food thus defines our relationship to it as one of consumption. As it had been labeled and framed as Other, the relationship is further defined as consuming the Other. This consumptive relationship may foster cultural appropriation and/or the commodification of peoples, food, and neighborhoods.

Conclusion

The culinary tourist has many popular options should they select a destination close to home or prefer to embark on a global journey. Taking classes at a famous culinary institute, attending food festivals, and going on a food tour, all offer unique experiences for engaging with new cuisines and cultures. These activities also offer the culinary tourist the opportunity to observe and reflect upon the ethical issues that may arise,

such as culinary slumming, cultural appropriation, and representations of the exotic other.

Food Trade and World Trade Organization: Agriculture Agreement

David Jackson

University of Arkansas, Fayetteville, USA

Synonyms

Agricultural economics; Free trade; Global trade; Globalization; Tariffs

The World Trade Organization (WTO) Agreement on Agriculture (Agriculture Agreement 1994) is the primary multilateral trade agreement that addresses international agricultural trade. The preamble to the Agriculture Agreement outlines the objectives of its negotiation. The first objective is “to establish a fair and market-oriented agricultural trading system.” To meet that objective, a two pronged approach is outlined: (1) negotiation of commitments on agricultural support and protection and (2) more operationally effective GATT rules and disciplines. The result of the

negotiation and rules is to be the “substantial progressive reductions in agricultural support and protection sustained over an agreed period of time, resulting in correcting and preventing restrictions and distortions in agricultural markets.” Thus, to establish a fair and market-oriented agricultural trading system, the Agriculture Agreement requires countries to reduce the support or protection they provide to their agricultural industry substantially over time.

To reduce the support and protection, the agreement provides four specific areas within which binding commitments should be made: market access, domestic support, export competition, and sanitary and phytosanitary issues. The last area has been codified into a separate agreement (see Agriculture Agreement Part VIII, Article 14), the WTO Agreement on the Application of Sanitary and Phytosanitary Measures (SPS Agreement), which is discussed in a separate article. The Agriculture Agreement provides a framework for negotiation of the remaining three pillars: market access (Part III, specifically Article 4), domestic support (Part IV, specifically Article 6), and export competition (Part V, specifically Article 8).

Finally, the Agriculture Agreement contemplates concerns about the potential effects of the implementation of these negotiated commitments, specifically in developing countries. First, there is special and differential treatment (Part IX, Article 15), which extends the timeframe to implement either the reduction commitments or for least developed countries, an exemption from any reductions. Also, the preamble contemplates specific interest in the development of tropical agricultural products and also products that would diversify production from illicit narcotic crops. Finally, the agreement includes food security, environmental protection, and the potential negative effects of reform on net food importing countries as concerns that should be kept in mind in the negotiation of an equitable agreement.

Market Access

The first pillar of the Agriculture Agreement is to promote market access, through specific import

tariff commitments. This promotion is achieved in a three-part process – one, by converting all non-tariff measures into ordinary customs duties (a process known as “tariffication”); second, establishing a maximum level of tariffs to be applied per product (the binding commitments or concessions); and third, substantially reducing those bound tariffs over time. To address the conversion of measures into customs duties (import tariffs), the agreement notes a variety of nontariff measures should not be maintained, resorted to, or reverted to (Article 4.2) including quantitative import restrictions, variable import levies, minimum import prices, discretionary import licensing, nontariff measures maintained through state-trading enterprises, voluntary export restraints, and similar border measures (Article 4.2 Footnote 1). By transferring these measures into “ordinary customs duties,” more transparency about the agricultural import process and expected costs could be realized.

In order to provide a safety valve to address surges of agricultural product imports, a special safeguard mechanism was also created to permit limited government intercession during periods of surging import volumes or rapidly dropping prices, by allowing a government to impose a special import tariff (of up to an additional third of the amount of the normal customs duty) for a limited period of time.

For surging import volumes, the volumes of agricultural products must exceed a “trigger level,” a threshold, which would be based on a consideration of the “market access opportunity” of a particular product (Article 5.4). Market access opportunity is defined as a calculation of imports as a percentage of the corresponding domestic consumption, considered during the 3 preceding years for which data is available (Article 5.4). This market opportunity analysis would set trigger levels based on a three-tier system where greater import saturation into the domestic market would permit a lower trigger level percentage for the imposition of special safeguards: for market access below 10%, the trigger would be 125%; between 10% and 30%, the trigger level would be 110%; and greater than 30% the trigger level would be 105% (Article 5.4(a)–(c)).

For rapidly dropping prices, the import price (c.i.f. average unit price for the imported good) is compared to a domestic trigger price (based on a 1986–1988 average reference price) (Article 5.1(b)). For import prices on a shipment that drop below the domestic trigger price (known as the “difference”), an additional duty can be imposed, in a five-tier system (Article 5.5):

	Difference	Duty
(a)	≤10%	None
(b)	>10% and ≤40%	30% of amount by which difference exceeds 10%
(c)	>40% and ≤60%	50% of amount by which difference exceeds 40% + (b)
(d)	>60% and ≤75%	70% of amount by which difference exceeds 60% + (c)
(e)	>75%	90% of amount by which difference exceeds 75% + (d)

Thus, for duties in categories c, d, and e, the special safeguard duties are calculated both progressively and cumulatively (e includes d, which includes c, which includes b) as the differences continue to exceed the threshold difference percentage amounts. Perishable and seasonal products can be considered based on their characteristics in determining time periods and reference prices (Article 5.6).

Domestic Support

The second pillar of the Agriculture Agreement is the reduction of domestic support measures that a member country provides to its own domestic agricultural industry producers; however, this reduction includes some exceptions. This domestic support is calculated by the overall amount that a government provides annually to agricultural production, an amount termed the “Aggregate Measure of Support” (AMS). The commitment to reduce domestic support is calculated based on the total amount of AMS and a bound commitment not to exceed a certain specified level of total AMS (Article 6.3). The total AMS is defined as “the sum of all aggregate measurements of support for basic agricultural

products, all non-product-specific aggregate measurements of support and all equivalent measures of support for agricultural products” and considers the commitments as the members have made in the individual country’s schedules (Article 1(h)). Members must make annual commitments to reduce the level of domestic support provided to their agricultural industry.

Specific payments are categorized by the effect they have on the agricultural economy, either by encouraging increased production of agricultural products or affecting prices for those products, or both. These categories are known informally as colored “boxes” of support (although the colors are not mentioned in the agreement itself): Green Box, which comprises payments that do not have any serious impact on agricultural markets; Amber Box, which comprises payments that distort agricultural production, markets, and trade; and Blue Box, which comprises payments that provide both for the support for producers and for limits in agricultural production.

Green Box subsidies are outlined broadly in Annex 2 and can be broadly defined as government programs that have no effect of providing price support to agricultural producers. There are 12 categories of government payments identified: (1) general services (research, pest/disease control, training, extension, advisory, inspection, marketing, infrastructure – such as electricity, roads, transport, water-by only capital works), (2) public stockholding for food security, (3) domestic food aid, (4) direct payments to producers, (5) decoupled income support, (6) government financial participation in income insurance and safety net programs, (7) payments for relief from natural disasters (either direct or through crop insurance), (8) structural adjustment assistance provided through producer retirement programs, (9) structural adjustment assistance provided through resource retirement programs, (10) structural adjustment assistance provided through investment aids, (11) environmental programs, and (12) regional assistance programs. There are many criteria for government programs to meet the qualifications for any of these exemptions, and the criteria can be quite detailed.

The Amber Box of subsidies count toward the member countries total AMS calculation and can be defined as any payment that is not exempted under Annex 2. These are payments that have to be reduced over time, but certain Amber Box payments are excluded from reduction including de minimis, developing country programs and production-limiting payments. The last category of payments, direct payments for production set-aside programs, are called “Blue Box” subsidies. In Article 6.5(a), these programs are further outlined into three categories: (1) payments based on fixed area and yields, (2) payments on 85% or less of the base level of production, or (3) livestock payments made on a fixed number of head.

Exports

The third pillar of the Agriculture Agreement addresses export competition, through limiting export subsidies. Export subsidies consist of payments made to agricultural producers based on international sales of agricultural products (defined in the agreement as “subsidies contingent upon export performance”) but also cover broader payments and guarantees made regarding financing of international sales, marketing of products globally, or indirectly supporting the incorporation of agricultural products into finished exported goods. In Article 9, several types of export subsidies are explicitly listed: (a) direct subsidies contingent on export performance to producers, cooperatives, or marketing boards; (b) sale or disposal of noncommercial stocks of agricultural products by governments or their agencies at lower prices than the comparable domestic prices; (c) payments on the export of an agricultural product that are financed through governmental action (direct or indirect), including payments imposed for a levy on the product itself or a raw agricultural product from which the export is derived; (d) subsidies to reduce marketing costs (other than widely available promotion and advisory services) which include handling, upgrading, and international transport; (e) internal transport and freight

charges on export shipments that are more favorable than for domestic shipments; and (f) subsidies on agricultural products contingent on their incorporation in exported products.

There are other export subsidy provisions in the Agriculture Agreement: (1) circumvention prevention (Article 10), (2) provisions for agricultural products incorporated into exported products (Article 11), (3) restrictions and prohibitions on agricultural exports (Article 12), (4) international food aid donor requirements (Article 10.4), and (5) flexibility in years 2–5 of the implementation as long as the cumulative quantities and payments remain in line with the committed totals. The last provision is also known as “downstream flexibility.” Further, developing countries are provided longer implementation timeframes and less reduction commitments.

Other Features of the Agriculture Agreement

There are other features of this agreement designed to assist in the incorporation of the provisions into each member country’s national agricultural policy. First, there are special provisions for developing and least developing countries. Article 15 recognizes that differential and more favorable treatment is required for developing countries, and least developed countries are fully exempt from reduction requirements. Second, there was set aside a period for implementation known in the agreement as “Due Restraint” (Article 13) but known more informally as the “Peace Clause.” The Peace Clause limited the retaliatory actions other members could take in response to members’ agricultural support programs, but the Peace Clause is no longer in effect, as it expired at the end of 2003. Finally, the agreement notes that it is a start to the reform process, that more work will be required, and that the agreement establishes an Agriculture Committee to effectuate that work and implement the existing agreement (Articles 17–20).

WTO Disputes Involving Agriculture Agreement

The Agriculture Agreement focuses on macroeconomic policy involving agricultural targeted fiscal outlays. The types of payments involved can be both broad and indirect, which means that these cases can involve direct payments for actions or indirect payments for inaction depending on the intent and effect of the specific outlay. While the Agriculture Agreement solely encompasses agricultural products, governmental programs that extend beyond agricultural products can also be considered in conjunction with the Agriculture Agreement with respect to those agricultural products. Many of the cases address the relationship between the Agriculture Agreement and the General Agreement on Tariffs and Trade (GATT). Finally, these cases are inherently complex as the mechanisms in dispute are often not directly related to agricultural production, and the type of economic data to support the arguments is detailed and voluminous.

The disputes generally involve the invocation of several WTO/GATT provisions; however, for purposes of the list of relevant cases below, only the key discussions involving the Agriculture Agreement are identified in parentheses:

- European Communities – Regime for the Importation, Sale, and Distribution of Bananas DS 27 (preferential trade programs, Agriculture Agreement relationship to GATT)
 - Bananas III, as it is informally known, is a small piece of a much longer dispute between the European Communities and a preferential trading relationship with its former colonies known as the Lomé Convention and the worldwide market and banana-producing countries.
 - Ecuador, the United States, Mexico, Guatemala, and Honduras each were complainants in the dispute over the EC's preferential trade programs for bananas with the ACP (African, Caribbean, and Pacific) countries.
 - The complainants contended that the EC preferential trade regime for bananas violated GATT and WTO rules (Panel Report, para. 4.1), and in part, the EC claimed that the Agriculture Agreement superseded the requirements of GATT Article XIII (Panel Report paras. 4.19–4.20).
- The WTO Panel found that the Agriculture Agreement did not permit the European Communities to abrogate their responsibilities under Article XIII (para. 7.127, also in Summary 7.399(2) proviso 11.). Further, a specific provision of the Agriculture Agreement would need to be relevant in order to prevail (7.122), and in this case, the Agriculture Agreement provisions on market access and Article XIII were seen as complementary, not in conflict (para. 7.126).
- The Appellate Body upheld the Panel's decision on Article XIII (Appellate Body Report para. 255(d).
- European Communities – Measures Affecting Importation of Certain Poultry Products DS 69 (imposition of special safeguards and trigger pricing calculation and analysis)
 - During the GATT XXVIII Oilseeds negotiations, the EC implemented a new tariff rate quota for frozen poultry and contemplated special safeguards if the price of poultry were to dip below a certain price threshold (Panel Report paras. 9–12).
 - This case determined the trigger price for safeguards to be the c.i.f. price only, and further, it was the actual price, not a representative price. Finally, the case also negated the need for any finding of injury or damages prior to the implementation of safeguard actions.
 - Brazil argued that the “trigger price” for safeguards should include both the c.i.f. price and import duties, where the EC asserted that the trigger price should only be calculated based on the c.i.f. price itself (Panel Report para. 276).
 - The Panel majority found in favor of Brazil and thus that the EC had failed to apply the special safeguard provisions in accordance with Article 5.1(b) of the Agriculture Agreement (Panel Report paras. 281–282).

- Interestingly, one member of the Panel dissented, arguing that the trigger price should only be the c.i.f. price itself. The dissent was a particular foreshadowing, as the Appellate Body overturned the Panel, holding that the trigger price was the c.i.f. price only, not including customs duties (ABR paras. 153, 172.h).
- The ABR further found that the use of a representative price for calculating the special safeguard duties was not appropriate and instead held that the c.i.f. actual price for the actual shipment should be used (ABR paras. 171, 172.i).
 - Also, the Panel found that no finding of “injury or damage” was required to impose special safeguard provisions, a holding that was not considered in the appeal.
- India – Quantitative Restrictions on Imports of Agricultural, Textile, and Industrial Products DS 90–93, 96 (import restrictions and balance of payments necessity)
 - As part of a complaint regarding broad import restrictions imposed by India, the United States, Australia, etc. claimed that some of the tariff lines (710 out of 2411 or 26%) extended to agricultural products and that those agricultural import restrictions violated Article 4.2 of the Agriculture Agreement.
 - The case explored the interaction between the Balance-of-Payments provisions in GATT Article XVIII:B and the Agriculture Agreement and found that the import restrictions imposed by India were consistent with Article 4.2 of the Agriculture Agreement (Panel Report 6.1(ii), aff. ABR p. 154).
 - Canada – Measures Affecting the Importation of Milk and the Exportation of Dairy Products DS 103 (export subsidies, specifically definitions of payment and governmental action)
 - The United States and New Zealand complained that Canada through its government-controlled pricing arrangements for milk and dairy products violated the Agriculture Agreement’s prohibition on export subsidies.
 - The case is noteworthy, as the first WTO dispute involving export subsidies.
 - The Canada Dairy case defined an agricultural subsidy, a payment, the phrase “financed through governmental action,” and established procedural rules about order of analysis (agricultural subsidies first under the Agriculture Agreement then the Subsidies and Countervailing Measures (SCM) Agreement) and evidentiary rules for burden of proof.
 - United States – Tax Treatment for “Foreign Sales Corporations” DS 108 (export subsidies and foregone tax revenue (specifically for agricultural products))
 - The European Communities claimed that the United States through its legal treatment of taxation for Foreign Sales Corporations violated the Subsidies and Countervailing Measures Agreement and for agricultural products, the Agriculture Agreement.
 - The case discussed whether the foregone tax revenue was considered a payment by governmental action.
 - The Appellate Body found that the treatment of taxes was an export subsidy that was inconsistent with Article 10.1 and Article 8 of the Agriculture Agreement. In the subsequent Article 21.5 FSC case, the Appellate Body found the subsequent laws to be inconsistent with Articles 3.3, 10.1, and 8 of the Agriculture Agreement.
 - Korea, Republic of – Measures Affecting Imports of Fresh, Chilled, and Frozen Beef DS 161, 169 (domestic support and calculation of AMS)
 - The United States and Australia each claimed that Korea’s dual beef marketing (price stabilization) regimes, the Livestock Products Marketing Organization and the

- Simultaneous Buy Sell system, were in violation of the Agriculture Agreement, specifically, exceeding the amount of domestic support agreed upon by Korea in its AMS schedule.
- The Appellate Body determined that Korea's domestic support calculation was incorrect but reversed the Panel's determination of de minimis, calculation of AMS and total AMS, and was unable to determine whether the amount of total domestic support exceeded Korea's commitments (para. 186(b)–(d)).
 - Chile – Price Band System and Safeguard Measures Relating to Certain Agricultural Products DS 207 (tariff rate variability based on pricing fluctuations)
 - The Chilean price band system allowed for flexible tariff adjustments to be applied on imported agricultural products based on fluctuations in international prices.
 - The Appellate Body affirmed the Panel's finding that this price band system was a violation of Article 4.2, as it was a border measure, and not converted to an ordinary customs duty (para. 288(c)(i), (iii)).
 - The subsequent amended Chilean price band law was still found to be inconsistent with the Agreement on Agriculture in the Recourse to Article 21.5 Appellate Body Report (para. 254(b) affirming the Panel's determination).
 - European Communities – Export Subsidies on Sugar DS 265–266 (export subsidies)
 - The European Communities provided subsidies for various categories of sugar transactions, including support for sales below the cost of production and cross subsidization of other sugar transactions, effectively considering the subsidy more broadly based on its impact not just the direct payment of a subsidy for a specific transaction itself.
 - The Appellate Body in its review of the Panel upheld the determination that the European Communities support fit the definitions of both “payments” and “financed by virtue of governmental action” and thus, was inconsistent with Articles 3.3 and 8 of the Agriculture Agreement (para. 346(f)).
 - United States – Subsidies on Upland Cotton DS 267 (domestic support- export credit guarantees, export subsidies)
 - The United States through its various cotton program subsidies (marketing, loss, counter cyclical, and export guarantees) had developed a financial safety net for cotton producers.
 - The Appellate Body found that these subsidies were inconsistent with Articles 3.3, 8, 9.1(a), and 10.1, although there was some dissent about export guarantees being subject to export subsidy commitments under Article 10.1 (para. 763(d)–(f)).
 - Further, the Appellate Body considered the application of the “Due Restraint” (Peace Clause) to the subsidies and found that the provision did not exempt the inconsistency (para. 763(b)).
 - In the subsequent review of amended US cotton subsidy programs, the Appellate Body for the Recourse to Article 21.5 found that these programs were still inconsistent with Articles 8 and 10.1 of the Agreement on Agriculture (para. 448(b)(iv)).
 - Turkey – Measures Affecting the Importation of Rice DS334 (import restrictions and discretionary import licensing)
 - Turkey managed rice importation through the granting of an import license called a Certificate of Control (Panel Report, para. 2.34(a)).
 - Turkey would deny or fail to grant these Certificates of Control outside of the tariff rate quota, which was found to be a violation of Article 4.2 of the Agriculture Agreement (para. 8.1).

Food and Ethics Issues in the Agriculture Agreement

The WTO Agreement on Agriculture is essentially the implementation of a free trade philosophy applied to the agricultural marketplace and advocates that governments of member countries limit the amount of economic interference made to promote domestic production. On its face, the Agriculture Agreement doesn't seem to create an ethical issue for food production. In fact, the Agriculture Agreement seeks to improve transparency in agricultural markets, which should make them more efficient. However, efficient markets in a free trading system favor efficient producers and punish less efficient producers. Further, agricultural markets are traditionally more volatile with wide swings in prices possible based on seasonal production, and supply and demand further affected by perishability.

It may be simplistic to offer that people must have food to survive – after water and air – it is the most basic of needs. For industrial goods there may be a need that they provide, but there is more substitution available among these goods. But food is far more important, and less substitution is available in agricultural markets, because of perishability, cultural norms, and the obvious primacy of food for human life. Further, transportation of food is more difficult because of perishability, and the amount of infrastructure and time-to-market considerations are different than for industrial goods. In fact the United Nations has been advocating for a “right to food” in its discussions of agricultural production in the twenty-first century. The UN has even appointed a “special rapporteur” on the right to food, Olivier de Shutter, to act as an independent expert appointed by the Human Rights Council.

Since agriculture provides either the raw ingredients for food, or food itself, there's a strong incentive for governments to intervene in the agricultural markets to ensure food security. A lack of food security creates political instability – hungry people overthrow governments. Also since many developing countries' economies rely on agricultural production as one of the main sources of

income, there is a much higher expectation of government support for developing country's agricultural producers; since poor people cannot buy food, and thus are hungrier than the nonpoor, they are more likely to overthrow governments even if food is available but too expensive to purchase. Because developing countries are likely less efficient producers of agricultural products, the free trade paradigm would likely punish rather than reward these producers, with lower prices than would permit producers to thrive in comparison to more efficient foreign producers, creating a rich farmer-poor farmer divide. Thus, there is a continual focus on the needs of developing and least developing countries in discussions of global trade.

It is under this backdrop of farmers, prices, and food security that discussions about the future of global agricultural trade occur. The various cases involving the Agriculture Agreement so far have explored specific countries and specific agricultural markets where economic distortions may have occurred beyond the agreed-upon levels. The Agriculture Agreement itself was a start, and not the end of a resetting of the economic distortions that have plagued global agricultural markets for centuries.

In November 2001, the WTO convened the latest round of trade negotiations, the Doha Development Agenda or the Doha Round. Agriculture plays a prominent role in the negotiations, which aim to continue the work of decreasing domestic support, eliminating export subsidies, and improving market access, as identified in the original Agriculture Agreement. There is continued discussion about special and differential treatment for developing countries and a special subcommittee for cotton has been formed. There is also a consideration for Non-agricultural Market Access (NAMA) and the balance of NAMA and agricultural trade market access. On August 1, 2004, a framework for negotiations was established, and in 2005 at the Hong Kong Ministerial Conference, a Ministerial Declaration was adopted. The Doha Round negotiations are ongoing.

The latest round of negotiations wrapped up in Bali, Indonesia, in December 2013. Specific

Ministerial Decisions regarding agriculture included a recognition of the need for “General Services” for the agricultural sector such as rural development, land rehabilitation and soil conservation, and commercial infrastructure for farmers. The Ministerial Conference recognized the need for public stockpiling of “traditional staple food crops” to promote food security. There were separate decisions considering tariff rate quotas as import licenses and working to eliminate export competition as originally conceived in the Hong Kong Ministerial Conference. Finally, the negotiations specifically called out the cotton agricultural sector for continued focus given the role of cotton farming in developing countries especially in Africa. However, in each of the texts, there was an explicit understanding of the work that was yet to be finished.

Food Waste

Erica Giorda
Sociology, Michigan State University, East
Lansing, MI, USA

Introduction

Food spoils: for centuries the fight against food decay has been central to the survival of human civilizations. Protected storage facilities, brining, freezing, drying, refrigerating, and more recently canning and adding chemical preservatives: by all means humans have tried, and to a point succeeded, to preserve food and keep it from spoiling. Yet, in the twenty-first century, the world is divided between countries that are still struggling to keep their food reserves safe, where populations struggle with hunger, and countries that overproduce and throw away up to 50% of

their agricultural production and whose populations struggle with overnutrition.

Current research on food waste, while growing, is still in a developing phase. A significant amount of applied research on the subject is targeted to the food industry, with the aim to reduce wastage during the production phases and control for damaging compounds in outgoing waste to limit pollution. In the last 10 years, different projects and a worldwide round of new surveys helped creating a more detailed picture of how food goes wasted worldwide, but data are still fragmentary and likely to underestimate the size of the problem (FAO 2011; USDA 2009). A larger project on human waste (the WRAP project in GB) is now devoting more interest to food waste in particular; the University of Bologna has a large applied project on food waste reduction (Last Minute Market), but others (the Garbology project) just ended. At the same time numerous grassroots organizations and individual activists are engaging the subject. These last initiatives, as much as the bulk of the institutional programs, are mostly devoted to tackle household waste through educational tools (website, recipes, blogs).

Even if wasting food is occasionally used as a means to show power and wealth, there are also many well-ingrained cultural norms that strongly discourage it. In the nineteenth century, avoiding food waste was still a clear concern even for well-heeled urban households in the industrialized world. Household management manuals from the late 1800s offer suggestions to better manage iceboxes and home storage and recipes to make the most of leftovers (Strasser 1999). Industrialized countries were still fighting hunger in the twentieth century: the Great Depression after WWI, the famine in Europe during and after WWII, and even minimal rationing in the United States in the same period encouraged households to manage their food supply tightly. Governments on both sides of the ocean issued pamphlets and educational materials to help households (or, to be precise, the ladies of the houses) to be thrifty and avoid wasting food. Nowadays the many websites and pamphlets and books devoted to the same goal repeat very similar suggestions,

yet household food waste adds up to about 100 kg per person a year in North America, Europe, and Oceania. In these same countries, food losses throughout the food production chain total about 300 kg per person each year: about $\frac{1}{2}$ of it is discarded before even reaching the processing plants (FAO 2011).

Attitudes surrounding food waste tend to be idiosyncratic: wasting food is generally frowned upon, yet the intertwined and frequently contradictory moral, economic, social, and institutional pulls that spur wasting make it difficult to estimate what could be an achievable level of waste and how to effectively reach it.

To understand food waste, it is important to look at different factors. The first part of this entry provides an analysis of the food distribution chain aimed at understanding at what stages waste occurs and what are the main causes for it. Subsequently, Boltanski and Thévenot's (2006) work on convention theory helps to highlight the various kinds of solution proposed to deal with food waste at different points of the chain in relation with the different kinds of moral values attached to waste within different polities. Within this framework, the social and environmental impacts of food waste are analyzed, and recent lines of research and public engagement are discussed.

Accounting for Food Waste?

Tons of edible food go wasted, and tons of food scraps head to landfills every day, posing challenges to those who handle them, increasing environmental pollution, and adding costs throughout the food production chain. At the same time, millions of people suffer from hunger: this striking paradox makes the issue of food waste central to the quest for global sustainability.

In a 2010 report, the European Commission (2010, p. 24) defines food waste as raw or cooked food materials that do not reach the final consumer or are discarded without being consumed, at any time between farm and fork. The US Department of Agriculture (2009, p. 1) distinguishes between “three general types of losses: (1) loss from

primary (e.g., farm) to retail weight; (2) loss at the retail level; (3) loss at the consumer level.” These definitions connect food waste to the global food production and distribution chain, whose complexity makes the food waste problem daunting. Additional elements further compound the picture, because by wasting food we also deplete other resources. First, water waste and pollution are a crucial side effect of food waste and are present at every level of the food chain (Lundqvist et al. 2008). Second, as food production is resource intensive, wasting food increases nonfood waste collateral to food production: fertilizer runoff, pollution caused by CAFOs and fish farms, the methane generated by food rotting in landfills, etc. Finally, we should account for a significant energy loss: about 230 trillion BTU a year in the United States alone are used to produce the amount of food that ends up in the landfill (Cuéllar and Webber 2010).

When and Where Is Food Wasted?

Food is wasted differently in different areas of the world: the most striking contrast is due to the fact that the industrialized world wastes little during the processing phases and a lot at the end of the chain (consumption). In less industrialized, developing, and underdeveloped countries, food waste is minimal at the consumption level and high during processing (FAO 2011). In these areas, faulty storage and antiquated processing methods appear to be the most relevant cause of food waste, combined with crumbling infrastructures, improper weather protection, and lack of investments in this sector (Smil 2004). Detailed research on food waste in the nonindustrialized world is still minimal, and while the food distribution chain and the distribution of waste in the industrialized world are better researched, most data available are still rough estimates (FAO 2011).

At each link in the supply chain, there are different elements that contribute to create waste. Exogenous and endogenous aspects affect waste throughout the production phase. Exogenous waste is created by non-preventable events: crop damage caused by weather or pests, animal illnesses, and so on. These are especially significant in the nonindustrialized world, but they can of

course occur everywhere: global climate change is expected to exacerbate these issues. Endogenous waste is caused by the way the globalized food distribution system is set up. Interestingly, the amounts of food losses and/or wastage at the production level are not significantly different throughout the world, but the causes for loss and waste are very different.

Industrialized agricultural production is set up for *overproduction* because only the best quality produce will reach the market, and wholesalers and distributors need to have an array of producers ready to deliver at any given time (Stuart 2009). Produce that does not meet the aesthetic standards set up by either the buyers or national and international institutions will not be harvested, or it will be thrown back in the fields after harvest. For example, until 2011 the EU prohibited the sale of irregularly shaped, yet safe to eat, vegetables. Only in few cases soup kitchens and food pantries are able to distribute small parts of this lost harvest. On the distribution front, farmers who are not able to deliver their produce at the time required by the buyer risk not to be able to sell their crop at all, while overproduction in some areas might flood the market making it too expensive for some farmers to even harvest. Current estimates point out that about 50% of farm production is discarded in industrialized countries before reaching the final consumer (FAO 2011).

Another wasteful sector is the fishing industry: in many cases bycatch fish cannot be brought to shore and is put back in the water even if dead; in the farm animals sector, intensive feeding operations expect a fixed degree of mortality despite the widespread use of antibiotics (Lundqvist et al. 2008; FAO 2011). Transportation is another link of the chain where both external and institutional factors determine waste: the presence of a proper infrastructure reduces waste and facilitates the movement of food. In countries where the infrastructure is poor, even durable food gets wasted in transport, and nondurable foods cannot be shipped at all. Significant amounts of food spoil during transportation in warm areas where refrigeration is not available and packaging is primitive (FAO 2011).

In the production phase, food waste, from peels to carcasses, is costly to dispose of and sometimes dangerous, but food processors have all the incentives to minimize waste. Industrialized meat packing plants, for example, increase the amount of meat that is not detached from the bones: hygienically safe methods to reduce waste have been developed, but – as the 2012 public outrage against “pink slime” demonstrated – consumers are not necessarily keen to buy the final product.

At the marketing stage, in the industrialized world, the amount of food waste varies greatly with respect to the different categories (canned, frozen, packaged, fresh, dairy, etc.) of food sold. Fresh produce is the most perishable item on the shelves, followed by dairy products. Moreover, for marketing reasons, stores are compelled to keep the shelves overstocked, which promotes waste. Bigger chains as Walmart have developed very efficient ways to manage stocks and move the burden of disposing waste either on producers or consumers: they demand producers to manage their shelf space and keep it stocked and up to date and use price rebates to lure consumers into buying more than they need (Stuart 2009).

Food safety and hygienic standards and pre-determined portions affect the amount of food wasted by institutions (schools, hospitals, prisons, etc.), where recycling and reuse of leftovers is impossible, portions are not necessarily geared to the needs of the recipients, and standardized menus leave little possibility of choice. The larger portions that proliferated in the last 15 years in the fast food industry have a similar effect.

Finally, about 30% of the food households acquire goes wasted in the industrial world (WRAP – Waste & Resources Action Programme 2007; USDA 2009; FAO 2011). The large amount of food waste at this level has multiple causes. First and foremost, as long as food is cheap and provisions are abundant, households do not have huge incentives to waste less. Consumers are also confused by “best-before” and “sell-by” dates, which do not necessarily imply food is not edible after that date, but are frequently perceived as so. USDA (and other agencies) food safety tools for households support this tendency, as they encourage throwing away any food item that

looks suspicious. Lack of knowledge on how to cook or reuse leftovers, the presence of kids in the household, lack of organization, and limited time to spend in the kitchen are also likely to increase food waste (WRAP 2007).

The Moral Economies of Food Waste

In a world where millions face hunger, wasting almost half of the food we produce looks ominous: it hurts human decency that people are starving while so much food goes wasted. This striking contrast drives much of the efforts of institution and activists alike, but solutions that only look at making the distribution chain more efficient or try to educate consumers to be thrifter might miss the point. While it is the contemporary presence of hunger and waste that mostly fuels moral calls (the infamous “bread lines knee deep in wheat” of Great Depression memory), reducing waste does not per se affect hunger and, in some cases, might even exacerbate it for people who rely on discarded food for their survival (Stuart 2009).

Boltanski and Thévenot’s (1991) work on justifications outlines several conflicting sets of values (moral worlds) that govern behavior in contemporary western societies. Boltanski and Thévenot outline six “worlds,” governed by distinct values: the Domestic world, the Civic world, the Industrial world, the Market world, the Inspired world, and the world of Fame. By analyzing how worth is attributed in the different contexts, they argue that conflicts arise when certain actions are evaluated according to principles pertaining to different worlds or when the set of values that justifies actions in one world is forced upon actions or things pertaining to another world. In our case, thriftiness would be a Domestic virtue that is frequently emphasized by food waste activists, but it has no value in the world of Fame, where conspicuous consumption is a way to acquire status, and it contradicts the goals and values of the Market world, where increasing consumers’ spending is a crucial goal. This perspective helps in highlighting some of the contradictions that affect food waste management and reduction in the industrialized world.

Conflicting Values Surrounding Food Waste

Value conflicts around food production, consumption, and waste are especially evident in the industrialized countries, as they stem out the industrial agricultural processes and the commercial practices of the food industry at large. Revisiting the food chain within the framework of convention theory highlights the tensions within the different actors and sets of values governing the various links.

Most of the industrial food production chain is governed by the values of the Industrial world: here the higher common principle is efficiency, and “the ordering of the industrial world is based on the *efficiency* of beings, their *performance*, their *productivity* and the capacity to ensure *normal operations* and to respond usefully to *needs*” (Boltanski and Thévenot 1991, p. 204). The way waste is produced and treated at the production stages of the chain has mostly to do with efficiency and productivity: to stay on the safe side and secure enough production to cover possible exogenous losses, farmers tend to plant more. Quality standards – a measure of value in the Industrial world – influence how much of the crop can reach the market, and safety issues and the timing of subsequent crops discourage or prohibit gleaning. Farmers act in order to maximize their outcome and control costs: when a crop is overabundant, or partly damaged, it is cheaper to let it rot in the field than harvest it.

The processing sector has been so far the most effective and motivated to tackle waste, as at this stage it is difficult to pass it over other links in the chain and the economic advantages of wasting less and increased productivity are evident and valuable in the Industrial context. Upgrades and fine-tuning of the production cycles increase efficiency and lead to significant waste reduction, while repurposing scraps (peels, juices, meat scraps, etc.) as raw materials for pet products or nutraceuticals (Zall 2004) increases productivity and creates additional revenues. Waste management at this stage seems not to be afflicted by conflicting values, and it works well.

An interesting tension is visible at the marketing and distribution levels: appealing to Civic values of solidarity and responsibility, since the 1990s, producers, wholesalers, and retailers have

relied on food banks to manage surpluses. By diverting damaged or nearly expired products to food banks and soup kitchens, wholesalers and retailers do not only reduce their landfill bills but can obtain tax rebates and positive news coverage for free. Food banks are now a highly efficient industry in the United States and are gaining popularity in the EU too. In recent years more agricultural producers are also using this channel to dispose extra production or lesser quality produce. This solution fosters solidarity and provides an outlet for food otherwise destined to the landfill and contemporarily exacerbates the stigma against the poor as it delivers second-class food to those who do not have access to the market. It has been argued that it might also reduce the responsibility of governments in fighting poverty and of the food industry to better deal with systemic food wastage (Poppendieck 1999; Stuart 2009).

Other waste disposal programs appeal to environmental values to propose solutions that transform food scraps from waste to resource: experimental animal feed operations are tapping the restaurant industry and smaller retailers to convert leftovers and wasted food into – mostly – swine food. This practice is well developed in various Asian countries and used worldwide in small farming operations (Westendorf 2008). Bio-gas production through digesters is another option that is available and frequently used in agricultural setting as a way to dispose waste and produce energy for farms. Some restaurant chains (Baja fresh, Burgerville) are also setting up internal composting/biodigesting programs that collect the food and the recyclable plates and silverware used in their location, as part of environmentally conscious brand programs that exploit environmental values to increase market visibility.

Further contradictions appear at the consumption level: low food prices, large availability of food, and aggressive marketing campaigns do nothing to suggest the need for constraint; producers and distributors thrive on their ability to convince consumers to buy more, as this not only creates profits but also shifts the burden of waste disposal from the distributors to the consumers (Stuart 2009). On the other hand, interventions aimed at curbing consumers' waste are rarely

aggressive and rely mostly on educational tools, whose content did not change significantly since the Great Depression: they make appeals at Domestic values of thriftiness and decorum and Civic values of social responsibility. From the academic perspective, this is the most explored and debated link of the chain. National governments and government-sponsored groups, as well as a number of activists and academics, are studying domestic food waste and suggesting possible solutions consumers can pursue to reduce the amount of food they waste. One common finding is that households do not have a clear perception of how much food they waste, and they tend to underestimate it (WRAP 2007). Proposed solutions are addressed at the Domestic environment and foster decorum, thriftiness, and “household’s arts”: teaching how to use leftovers, storage management, and organizing grocery shopping are typical examples. Education alone, however, rarely changes behaviors when the surrounding infrastructure and the local culture are not conducive to waste reduction. The latest lines of research are looking at how effective the institutional educational projects are in changing consumers’ habits with respect to food waste, and reveal sobering findings. Appeal to Domestic values alone seems to bring little change: structural limitations such as lack of space to devote for separate garbage bins and tight schedules that favor take-out meals trump appeals to better organization, plus the low cost of food itself does not justify the extra effort unless higher orders of values are engaged. Increasing trust in institutions and a strong system of incentives and supporting tools are more effective tools to curb wastage (European Commission [DG ENV – Unit C2] 2010), moving the possible solutions to food wastage more in the realm of Civic engagement.

Finally, one specific group, acting freely outside the boundaries of institutions, seems to follow mostly the values pertaining to the Inspired world. Positioning themselves visibly outside institutional boundaries, freegan activists scavenge supermarkets’ garbage disposal areas to rescue wasted food, and groups such as Food Not Bombs distribute for free food they collect from stores at the end of the day. While some freegans

are moved mainly by necessity, many of them consider themselves activists fighting against the incongruences of capitalist society and present their activism against food waste as a cultural and political choice (Katz 2006; Stuart 2009).

An Institutional Problem

The conundrum surrounding food waste shows clearly in the contradictory policies that affect the food chain. At the beginning of the chain, values from the Industrial world (safety, efficiency, productivity, product quality) justify waste. Similar values promote waste reduction in the processing phases, but waste is justified again by Market values during distribution and marketing. Meanwhile, at the end of the chain, Domestic, Environmental, and Civic values ought to stimulate consumers and municipalities to save money and energy, reduce impacts, and protect the environment.

International governance bodies and national safety standards have powerful influence on food waste. For example, the European Union defines the rules for agricultural production for member states and sets up production quotas. If a state produces more than the quantity allotted, it is supposed to reduce the production, dispose the product, and pay a fine. Fishing regulations not only define how much each state is allowed to land but also notoriously demand bycatch to be discharged. This issue afflicts the fishing industry worldwide, with discard rates of more than 10% (FAO 2011). Quality and safety standards also affect the agricultural production. For fear of contamination, leaf vegetables grown in fields where inspectors find wildlife tracks get discarded, slightly damaged items are not deemed fit for the market, and institutional and retailers’ quality standards reduce the amount of edible but aesthetically unpleasant fruits and vegetables that reach the shelves (Stuart 2009).

Once products reach the market, a relevant source of confusion and wastage is the dates stamped on perishable items. With the exception of few categories (meats, baby food, ready-to-eat salads), most food is still edible and safe well after the sell-by or best-before dates, but it gets discarded either by retailer or by consumers. The legislation defining the meaning and the scope of “expiration”

dates (best-before, use-by, sell-by, etc.) changes across countries (EU rules are different from US one and so forth), but consumers appear to be universally confused by these standards and tend to discard food after the date stamped on the package is passed or even when it is approaching (Strasser 1999; WRAP 2007; Stuart 2009).

Yet, the same institutions whose regulations foster waste production along the chain are affected by and concerned with overconsumption of energy, water, and fertilizers and the pollution generated by organic waste in landfills and as results of meat and fish processing. In few industrialized countries, landfill management practices have been implemented to harvest or burn methane, yet food still constitutes about 21% of garbage dumped into landfills in the United States (EPA 2012), increasing the burden on municipalities as landfill costs increase. The methane that leaks out of landfills where organic material is left to rot also increases the environmental burden of food waste.

Rising costs of garbage disposal are driving better post-consumption food waste collections, but they require well-managed composting facilities and separate collection bins for organic waste. Enforcing separate collection proved effective in many EU countries, but southern Europe is still lagging behind, mostly due to lack of proper funding and citizens' trust in the institutions responsible for managing the waste (European Commission [DG ENV – Unit C2] 2010), while public composting facilities are still rare in the United States where only 3% of food waste is incinerated or composted (EPA 2012).

refrigeration during transportation contribute to spoiling; lack of sanitation during processing phases further increases waste. In these areas, however, households waste very little.

In the industrialized world, food is wasted mostly at the very beginning and at the very end of the chain. Waste is high in the fields because the system is geared towards overproduction, and quality standards prevent farmers from providing the market with fruit or vegetables that are less than perfect. National and international regulations, constraint imposed by distributors, and price fluctuations also affect the amount of crops harvested. The other point in the chain where waste is significant in the industrialized world is at the consumption level: households waste about 30% of the food they buy. Wasting food not only has huge impacts on our ability to feed the planet but also causes direct and indirect environmental damage, affects water supplies, and has a high impact on energy consumption.

While the debate around food waste is growing in the western world, most of it is centered on the last link of the chain: the individual consumer. Systemic causes are rarely taken into account, as the consumers are considered to be individually responsible for their (wasteful) behavior. However, current research suggests that institutional factors also have huge impacts. Moreover, the contrasting sets of values characterizing the various links of the food chain foster contrasting attitudes towards waste and make it difficult to evaluate what an acceptable level of waste could be and how to define it.

Summary

In a world where millions of people are still struggling with hunger, almost ½ of all food caught or produced ends up wasted throughout the production and distribution chain. Food is wasted differently in developing countries compared to the industrialized world. In areas where poverty is endemic and infrastructure rudimentary, most waste occurs in the early links in the chain. Crops are more easily damaged and frequently harvested too early; rudimentary packaging and lack of

Introduction: Food Losses and Food Waste (Definitions)

The ethical issues related to food losses and food waste are very complex and to a large degree dependent upon at which part in the food supply chain they are identified. In this entry for reasons of clarity and space, the emphasis is placed on food waste occurring at consumer level and mainly on the discussion of the ethical responsibilities that can be said to exist at this stage. This can be justified as the largest percentage of waste occurs at consumer level. It is, however, important to remember that this waste is to varying degrees dependent on other factors such as retail strategies, production limitations, etc.

The definition of food waste is a contentious subject and often developed on a situational basis; definitions of food waste vary in what food waste consists of, how it is produced, at which stage of the food supply chain it originates, and where or what it is discarded from or generated by.

A study by the Swedish Institute for Food and Biotechnology (SIK) on behalf of the Food and Agriculture Organization (FAO) of the United Nations, *Global Food Losses and Food Waste*, distinguishes between food losses and food waste (Gustavsson et al. 2011).

Food losses refer to the decrease in edible food mass throughout the part of the supply chain that specifically leads to edible food for human consumption. Thus, food losses take place at production, postharvest, and processing stages in the food supply chain (Parfitt et al. 2010). They are a major factor in developing countries where infrastructures and technologies are poor. Such definition of loss also includes biomass originally meant for human consumption but eventually used for some other purpose, such as fuel or animal feed.

Food waste generally refers to the deliberate discarding of food that is “fit for purpose and perfectly good to eat” (Knight and Davis 2007). This occurs in the latter part of the food chain, in food companies, wholesaling, retailing, and households and is mostly common in developed/wealthy countries.

Smil (2004) also includes overnutrition in the definition of food waste. Overnutrition in this context signifies the gap between the energy value of *consumed* food per capita and the energy value of food *needed* per capita. In the European Union, until 2000, food waste was defined by the Directive 75/442/EEC and considered as “any food substance, raw or cooked, which is discarded, or intended or required to be discarded.” This directive was replaced by Directive 2008/98/EC where there is no specific definition of food waste, but just a broad description of “categories of waste.”

Other issues that are closely related to food waste although typically not discussed as food waste but rather as a question of sustainable use of resources are (excessive) transportation of foods and the use of resources as water, arable land, fertilizers, energy, etc.

Attempts have been made over several decades to quantify global food waste, motivated partly by the wish to highlight it in relation to global malnutrition. Such assessments are currently reliant on limited datasets collected across the food supply chain (FSC) at different times and extrapolated to show the larger picture. Each study analyzes food waste in a different way making it difficult to use one study to corroborate another. For instance, one report uses a caloric evaluation of the entire food supply, while another evaluates waste only at the consumer level, combining in-home and out-of-home meals.

The most often quoted estimate is that “as much as half of all food grown is lost or wasted before and after it reaches the consumer” (Lundqvist et al. 2008). More precisely, per capita food wasted by consumers in Europe and North America is estimated to be around 95–115 kg/year, while this figure in sub-Saharan Africa and South/Southeast Asia is only 6–11 kg/year. Such estimates are difficult to scrutinize but highlight the need for greater resource efficiencies in the global FSC.

Food Waste: Estimations and Impacts

A research carried out by Smil provides a global overview of losses and waste that take place “from

field to fork.” On average, only 43% of the products cultivated for food are actually consumed. Farmers are on a global average able to produce the equivalent of 4600 kcal/capita/day. In addition to the losses because of inefficiencies in the harvesting, transportation, storage, and processing stages, which cause an initial reduction (600 kcal), the conversion of food production (mainly grains) into food intended for livestock has the most significant impact on the amount of daily kilocalories actually available for human consumption. This conversion causes a further net decrease of 1200 kcal/capita.

While not really food waste per se, allocating food to animals raises many questions among those studying food security. Another issue along the same lines is the food used to feed companion animals that are not themselves considered as food sources. Even though food for companion animals often contains, e.g., parts of the carcass that are not usually used for human consumption, some resources suitable for human consumption are “lost” in the process. Finally, food retail distribution causes additional waste (equal to 800 kcal), leading to a usable caloric content of just 2000 kcal (Smil 2004).

Volumes of food waste vary from country to country. In the United States, losses at the farm level are about 15–35%, depending on the industry (Jones 2004). For the fresh vegetable industry, losses are naturally higher at 20–25%. The retail industry has high rates of waste at about 26%, while supermarkets, surprisingly, only lose about 1%. “Overall losses amount to somewhere around USD 90 to USD 100 billion a year” (Jones 2004) and “. . . households, in the US alone, throw away USD 48.3 billion worth of food each year” (Jones 2006). An average family of four persons in the United States wastes 60 kg of food per month (Martin 2008).

Food losses and wastage are also reported from Europe. According to a recent DG Environment study from the European Commission, the quantity of food discarded in the 27 member countries amounts to 89 million tons, or 180 kg per capita per year. Waste at home contributes the most significant percentage: it is equal to 42% of the total and amounts to about 76 kg/year/person

(60% of which could be avoided because constituted by edible food). The portion attributed to food processing (39%) and the portion from catering and restaurant services (14%) are also quite substantial (European Commission 2010).

On the national stage, the level of food waste can be exemplified as follows: in the United Kingdom, Knight and Davis (2007) estimate that "...about five million tonnes of food goes into household waste" and that "...total consumer and industrial food waste reach 17 million tonnes annually." Reports from Sweden suggest that families with small children throw away about 25% of the food they buy and that total losses and wastage in the food chain are close to 50% (Kungl. Skogsoch Landbruksakademien 2007). Figures are, however, uncertain. The Dutch Ministry of Agriculture, Nature and Food Quality has estimated that Dutch consumers throw away approximately 8–11% of food purchased (Parfitt et al. 2010), equating to 43–60 kg. As easily seen these numbers from different nations differ consistently. This is due both to national and regional differences in food culture, living patterns, prices, infrastructure, etc. and also to the lack of common methodologies and definitions.

Regardless of these methodological issues and the scientific uncertainty, it is important to recognize that food waste has significant consequences from a natural resource and environmental perspective.

In terms of food production, agriculture is responsible for a significant amount of total anthropogenic greenhouse gas emissions (GHG). Livestock production alone accounts for about 18% of total GHG emissions according to conservative estimations (Steinfeld et al. 2006). In addition, there are substantial environmental costs associated with transport, storage, processing, packaging, and improper disposal of discarded food. If discarded food is used for landfills rather than being properly disposed of through, e.g., composting or for biogas production, the organic content will generate gases, including methane, which is a very potent GHG (Knight and Davis 2007). The GHG emissions attributed to food waste are calculated by dividing by three the total GHG emissions contributed by the food

system, which is estimated at 9800–16,900 MtCO₂e/year (Vermeulen et al. 2012).

Wasting food also means wasting resources like:

- Energy (the calories in wasted food are never consumed, and therefore, the energy that went into growing, processing, packaging, and transporting food to the consumer is lost)
- Water (water losses accumulate as food is wasted before and after it reaches the consumer: calculations estimate that food waste accounts for more than a quarter of total fresh-water consumption globally)
- Land (arable land is used to produce food that is not consumed)
- Labor (the work of farmers to produce food is lost when food is discarded)

Besides environmental impacts, food waste also imposes an economic cost on consumers and retailers. Estimates for Great Britain also show that 30–40% of the annual production of discarded food has an estimated economic value equivalent to about €18 billion.

Food Waste Along the Supply Chain: Causes and Consequences

Food waste in the food system occurs throughout the supply chain. Food is lost for a variety of reasons at each stage: on farms, during processing, distribution, and storage; in retail stores and food service operations; and in households. As mentioned in the beginning, the loss occurs at different stages in the process in countries in the developing and the industrialized world. However, the significant inefficiency of the food system at different levels has received virtually no attention to date, resulting in a dearth of data that could otherwise illuminate key drivers of the problem or possible solutions (Stuart 2009).

At the farm level, food loss falls into two categories: (1) food that is never harvested and (2) food that is lost between harvest and sale. Produce may not be harvested because of damage caused by pests, disease, and weather or for

economical reasons: if market prices are too low at the time of harvest, growers may leave some crops in the field because they will not have their costs covered after accounting for the costs of labor and transport. Another cause of unharvested produce is food safety scares (e.g., in 2008 a warning was issued by the Food and Drug Administration in the United States of possible salmonella contamination in tomatoes).

Once crops have been harvested, culling is the primary reasons for losses of fresh produce. Culling is the removal of products based on quality or appearance criteria, including specifications for size, color, weight, blemish level, and brix (a measure of sugar content). Quantities vary significantly by product and situation. Processing facilities generate food losses mostly through trimming, when both edible portions (skin, fat, peels, end pieces) and inedible portions (bones, pits) are removed from food. Overproduction, product and packaging damage, as well as technical malfunctions can also cause processing losses, though these may be difficult to avoid. Proper transport and handling of food are critical throughout the supply chain, particularly with perishable goods that require cold conditions. Inconsistent refrigeration is less of a problem today than in the past, but it still occurs when cooling systems malfunction or human errors cause the cooling chain to break down (Segrè and Gaiani 2011).

Most of the loss in retail operations is in perishables – baked goods, produce, meat, seafood, and, increasingly, ready-made foods. The USDA estimates that supermarkets lose \$15 billion annually in unsold fruits and vegetables alone. Unfortunately, the retail model views waste as a part of doing business. Some of the main drivers for in-store retail losses include overstocked product displays (customers tend to buy more from fully stocked displays); expectation of cosmetic perfection (retailers feel compelled to have only produce of perfect shape, size, and color); inadequate pack sizes; availability of fresh, ready food until closing time; and expired “sell-by” dates (products are discarded when they are near their sell-by dates). Products are also discarded due to damaged packaging or

promotions that have passed (postholiday discards are most common). At the retail and endconsumer stages of the supply chain, perishables make up the majority of food losses due to the high volume of consumption and the food’s tendency to spoil. In terms of total mass, fresh fruits and vegetables account for the largest losses, followed closely by dairy and meat/poultry/fish.

Drivers for household losses include lack of awareness and undervaluing of foods (cheap, available food has created behaviors that do not place high value on utilizing what is purchased), confusion over label dates (label dates on food are generally not regulated and do not indicate food safety), spoilage (food spoils in homes due to improper or suboptimal storage, poor visibility in refrigerators, partially used ingredients, and misjudged food needs), impulse and bulk purchases (store promotions leading to bulk purchases or purchases of unusual products often result in consumers buying foods outside their typical meal planning, which then gets discarded), lack of meal planning and shopping lists, and over-preparation (cooking portions have increased over time and large portions can lead to uneaten leftovers; Parfitt et al. 2010).

Ethical Aspects of Food Waste

Food waste is seen as so obviously ethically wrong that it is seldom spelled out what the ethical issues related to food waste are. There are however many interesting discussions hidden underneath, e.g., people’s gut reaction drawing into question whether food waste is not a necessary price to be paid for the culture of affluence in the Western world that by many are seen as part of the good human life. In this light food waste becomes more a clash of values creating ethical conflicts than a mere accidental and correctable side effect. Further food waste can be understood more as a symptom of deeper problems connected to the relation between humans and nature than just an issue in itself.

In the next paragraphs, four areas where food waste raises ethical issues are presented. These are

food waste consequences for humans, food waste consequences for the environment, the relation between consumerism and food waste, and the relation between view of nature and food waste.

Consequences for Humans

Food waste can be considered an unnecessary waste of resources that could have benefited others. Food waste at the consumer level, however, can only seldom directly be utilized for helping people in need. Food thrown away in Western European households can hardly be made useful for those worse off in other places of the world. Indirectly though, a reduction of food waste could benefit those impoverished as the money saved from not wasting food could be directed toward them. Other factors than just a reduction in food waste are required. There is little gain for those in need of food, if the money saved from reducing food waste is directed toward other kinds of consumption such as buying more expensive cars, holidays, furniture, clothes, etc., in private households or building new societal infrastructure such as roads and shopping malls to accommodate a growing consumer society in the Western world. A reduction in food waste thus needs to be followed by other actions intended to benefit other human beings directly.

This raises the ethical question whether those who live in affluence are obligated not to waste food and instead use the saved resources to help others. If the answer to this is yes, the question then becomes: why is this so in the area of food waste, but not in other areas of consumption? Why is food so special that food waste seems self-evidently wrong, whereas the waste of resources connected, for example, to fashion is not debated to the same degree? And to what extent are humans compelled to change their consumption patterns to help those worse off than themselves (Aiken and LaFollette 1996)?

Consequences for the Environment

The production of food has negative environmental consequences. Much has been written on the consequences of different agricultural practices on the environment especially focusing on animal production. Some of these consequences are

detrimental to nature and the environment. Furthermore, if agricultural and animal products are not used for their primary purpose – i.e., to feed humans or animals – but are simply thrown away, this contributes to a waste of resources and a deeper pressure on the ecosystems: desertification; eutrophication; pollution of air, land, and water; depletion of scarce assets such as freshwater and phosphorous; and climate change are just some of the negative consequences that again have effects on humans (FAO 2011). As mentioned before, the problem is not simply solved by reducing food waste. Human beings consume and throw away food and material objects at a high speed. Reducing food waste in itself will not solve the problems, if not seen as part of a larger context focusing on reducing consumption in general.

Food Waste as Overconsumption

As described in the previous sections, there are many and often interwoven reasons for food waste. One that attracts special ethical attention is connected to affluence in Western societies that enables consumers to choose from a multitude of foods when they visit restaurants, canteens, supermarkets, and shops. The choice of the individual entails that all that is not selected risks ending up as food waste. Consumers indirectly pay for these products too as producers, retailers, canteens, etc. simply place the value of the expected waste on the products that are sold. Part of the money paid when shopping thus finance the multitude of choices we have when shopping and the luxury of not wondering what there might be to eat, but rather wondering what we would like to eat.

The question is: is this ethically wrong? Or could it be argued that it is up to consumer self-determination how they choose to spend their money? Obviously consumers are not supposed to spend money in ways that hurt other human beings, but as there no predetermined restrictions or limits to wasting resources as energy, land, water, etc. as long as consumers are willing to pay for a system that entails food waste, it could be argued that considering food waste as especially problematic seems arbitrary.

However, reasons for this reaction can be found. It is not that long ago – even in affluent Western societies – that food was sometimes a scarcity and hunger a sensation that most had felt. Throwing away food simply feels morally wrong, as it is such a tangible sign of richness bordering on decadence. While Western people eat whatever they want, they are confronted with news stories from not that far away where hunger is still a part of the everyday lives of nearly 900 million human beings. When dealing with a cultural phenomenon, it is hard not to react at such visible inequality in the world. Food waste thus becomes a symbol of human injustice that hits us right in the face (Edwards and Mercer 2007).

Nature and Food Waste

Another reason why food waste is experienced as ethically problematic is that it can be seen as disrespectful to the organisms, ecosystems, and biosphere that provided the food in the first place. Food is one of the most basic ways humans interact with the more-than-human nature that sustains their lives. Food is in that sense a participation in the rhythm of life on the planet where humans constantly stand in a very intimate relation with the world. The strong reaction toward food misuse can thus be interpreted as pointing to deep-seated experiences of human existence as being closely knitted into the beings and rhythms of a nature that is valuable and worthy of respect and love for its own sake, experiences that point toward gratitude and community. Throwing away food is a rejection of this understanding of nature as a relational subject and a reduction of it to an external object with only an instrumental value. Respect for the fruits of the earth and thankfulness toward the abundance of life that surrounds us have found expression both within religion and philosophy. The poet Gary Snyder has expressed it this way: *Every meal is a sacrament* (Snyder 1990). Food waste can thus be interpreted as a kind of “sacrilege.”

The strong reactions toward food waste can thus be understood by the illumination the phenomenon throws on distance between those who live in poverty and hunger and the ones living in affluence in the distance between Western

consumers and the more-than-human nature that they are embedded in. Food waste is not just an unfortunate by-product of Western culture, but a market-driven necessity in a culture of affluence. The distance between the way people relate to food in that culture and the way humans have related to food through the most of history is what makes the phenomenon so hard to accept.

Reacting to food waste on a personal level can be difficult as the discarding of food is often an unconscious/non-reasoned act. Following Ajzen’s theory of planned behavior, this kind of food waste can thus be seen as an action based on social norms and identity, external conditions, and habits (Ajzen 1991). Wasting food has become in some cases a persistent habit, and as such, it is very often a non-reasoned action and therefore it is not immediately influenced by normative social discussions. Food waste is an integrated part of life in Western consumer societies, and to change this, more than moralizing is needed.

Here raising awareness of the problem and developing a more community-oriented way of thinking of the role of humans in the ecological systems could be seen as a solution. Drawing on different traditions within the broad framework of ethics of nature, spiritual sustainability, ecocentric thinking, etc., we suggest that developing what Goleman has labeled an *ecological intelligence* (Goleman 2009) could be a way to address the issue of food waste as the change in behavior needed is embedded within a cultural context that needs to be changed, if the problem is not to be the problem of the individual consumer fighting a hopeless battle against a culture of affluence.

Summary

The definition of food waste is a contested subject and often developed on a situational basis; definitions of food waste vary in what food waste consists of, how it is produced, at which stage of the food supply chain it originates, and where or what it is discarded from or generated by. Attempts have been made over several decades to quantify global food waste: such assessments are currently reliant on limited datasets collected across the food supply

chain (FSC) at different times and extrapolated to show the larger picture. The most often quoted estimate is that “as much as half of all food grown is lost or wasted before and after it reaches the consumer” (Lundqvist et al. 2008). Food waste has environmental, socioeconomic, and ethical impacts. There are many contributing factors to food waste. Most importantly, it seems to be not just an unfortunate by-product of Western culture, but a market-driven phenomenon in a culture of affluence. It is one of the most visible symbols of the distance between rich and poor and between consumers and the more-than-human lifeworld that they are embedded in and dependent on.

Introduction

Food and film are a recognized subfield in film scholarship (Ferry 2003; Keller 2006; Zimmerman 2010; Bower 2012; Baron et al. 2014), and food and gender are thoroughly explored in women's and gender studies (Allen 1984; Counihan 1999; Bordo 2003; Avakian and Haber 2005; Inness 2011). This entry brings together these two areas by way of the concept of "food worlds." I shall begin with a brief description of the concept "food world," describe existing scholarship on food and gender and on food and film, and then show that most films assume and illustrate gendered food worlds.

I am using the term "food world" to refer to the meanings that food and the activities surrounding food and eating have for a person. Each of us bears particular relationships to eating and food, and these relationships are shaped by our experiences, as well as biologically and culturally influenced likes and dislikes. Our relationships to food have to do with the procuring of food, preparation of food, and, most importantly for my purposes, attitudes to and emotions regarding food and eating. Our food worlds also include how much time we spend thinking about food. They are constituted by our feelings about our bodies and how much time we spend thinking about them. They include how we react to feelings of hunger; how we experience the sensations of fullness and emptiness, that is, the meanings of the physical sensations related to food and eating to

us; and how we behave in response to those meanings. Is eating pleasurable? Anxiety producing? Different in different circumstances? One's relationship with food thus involves physical, emotional, and psychological aspects. It is this web of relationships between oneself and food that I call a "food world." We all inhabit food worlds, but our individual food worlds are different. Whether one is sensitive to these differences is also part of one's food world.

One's emotional relationship to food and eating is a significant part of one's food world. Both negative and positive emotions make up that world. Many feel negative emotions, such as "anxiety, guilt, fear, and shame" about "how we eat, what we eat, and, above all, how much we eat" (Iggers 1996). Most people also feel positive emotions about eating and food. The planning and preparation of food can bring great pleasure, especially when we make food for those we love. Food can comfort, and the sensual pleasures of eating can be intense and fulfilling. Anthropologists have introduced the concept of "foodways" and have analyzed film from the perspective of foodways. Food worlds seem to be a subset of foodways and to focus more on the personal meaning of food than the foodways perspective.

Though each of us has our own food world, there are discernable patterns that link these worlds according to group membership. I am interested in the gendered patterns evident in the food worlds depicted in film. First, I will introduce food and gender and then discuss both of these in relation to film.

Food and Gender

Much has been written about gender and food, especially women and food. Susan Bordo's *Unbearable Weight* is a classic of this genre (2003). As she points out, the history of Western philosophy identifies women with the body more than it does men, and devalues the body in relation to the mind, thereby devaluing women. Women's identification with the body is identification with appetite and desire, which, in this history, threatens reason and rationality. Appetites must be controlled by reason. But, paradoxically, women, considered weak in reason, are culturally

gifted with the role of control of appetites. This is very clear in traditional conceptions of heterosexual relationships, where women are supposed to control their sexuality, and that of males, by means of their refusal or acceptance. We also see this in the case of food and hunger. Women are not supposed to express hunger or the desire for sex or food. Their bodies are not supposed to be “excessive,” though this seems directly related to heterosexual sexual attractiveness. It is more acceptable for a woman to be overweight if she is “beyond” youth. In Hollywood, everyone is eternally young, and so women are eternally thin.

These norms for women affected by them require constant monitoring of food intake, both the amount of food and the kind of food. Sandra Bartky describes the disciplining of the body required by heterosexual femininity (1990). The constant monitoring of one’s body, its appearance, and the relation of this to eating is a part of this discipline. It is part of the heteronormative food world of a woman.

One might think that the “thin woman” obsession is peculiarly Western. It might once have been, but according to Bordo and others, this ideal has spread to much of the rest of the world, with the accompanying eating disorders and food-related behaviors. Bordo blames Western media, arguing that media images teach us how to see bodies. The availability and widespread consumption of Western media, including film, has altered preferred body types in cultures that previously accepted different body types. One oft-cited study showed that prior to the introduction of television to Fiji, there were almost no reports of eating disorders, and many women were substantial; thinness was ridiculed. After 3 years of exposure to *Baywatch*, young women showed eating disorders, and thinness was becoming the dominant body ideal (Becker 2004). The slim body ideal for girls and the muscled body ideal for boys are most influential among higher socioeconomic populations. As developing countries increase the middle classes, body dissatisfaction and eating disorders increase. Though much might be said about gender and food outside the United States, constraints on length require that this entry focus on food, gender, and film in the United States.

What about men and food? As Bordo pointed out in the 2003 edition of her book, body image problems are spreading to men. In fact, the dominant male body ideal, as displayed in magazines, television, and especially action films, is the lean and muscular body (Morrison and Halton 2009). Such bodies need fuel to power their actions. In action films, where these bodies are most often displayed, men regard eating as fueling. Men are allowed to be hungry, to be thirsty, and to express and fulfill their desires. Men can eat and drink as much as they want, with not too much concern about what is eaten. To be hungry, to have appetite, is to be masculine. To act so as to satisfy that hunger is also masculine.

There are exceptions to this, of course. Men are not supposed to be obese, though they may be overweight or out of shape with fewer negative social consequences than women. They may also be competent cooks, but only if they are professional, or semiprofessional. If they show too much interest in cooking and recipes, or are vegetarian or vegan, their masculinity may be questioned.

Food and Film

In bringing film into this analysis, one is faced with an enormous difficulty. It turns out that people hardly ever *eat* in movies. In a content analysis of the ten top-grossing Hollywood films between 1991 and 2000, researchers found that, although food did appear regularly in films, it was not typically the focus of the scene in which it appeared. Furthermore, it was rarely eaten by anyone in the scene. Alcohol was the most commonly appearing food or drink in these films and was much more likely to be ingested by someone than food (Bell et al. 2005). But it is the ingestion of food that best shows us the gendered norms of eating behavior and attitudes toward food.

In his account of the genre of “food films,” *Food in the Movies*, Steve Zimmerman makes this point. For most of the history of film, food was “ignored or hidden from view...” (Zimmerman 2010). This was in part for practical reasons. In the early days of film, prepared food would have had to sit under very hot lights for shot after shot and would not survive the treatment. But there are also aesthetic reasons for omitting

eating from films. Eating ordinary meals makes for slow, uninteresting viewing. The main uses of food in films do not require eating.

One of the main uses of food in film is as a prop, that is, “something that’s there while people do other things, like talk about love, family problems or matters more sinister” (Zimmerman 2010). In many films, a meal that is talked about or anticipated never arrives. In other cases, the food arrives, but is never actually eaten. When one observes a film in which people sit down to a meal at a table – something very common in films – one will see that those at the table may take one bite, but hardly ever two. Most of those at the table eat nothing. As we all know, scenes of meals at tables are not usually about food or eating. They are about other things, such as conflict, relationships, community, or power.

Another common use of food in film is as a “transition (or time-compression) device” (Zimmerman 2010, “Introduction”). We might see the preparation of a meal, or the beginning of the meal, or the table being set and then the washing up. Another major way that food is used in film is “to enrich the narrative by imparting a deeper sense of meaning to the story that is being told. Often this is accomplished symbolically and metaphorically to call attention to a significant event or a person’s character, lifestyle, class, race or economic status” (Zimmerman 2010, “Introduction”). For example, in the film *The Upside of Anger* (2005), which contains many kitchen and dining room scenes, a boyfriend of whom the mother disapproves is shown loudly slurping his soup.

Zimmerman’s exhaustive analysis of the use of food and eating in US film does not pay much attention to the gendered portrayal of food and eating. He does point out that, for years, films portrayed food prepared in homes by women, whereas in posh restaurants, it was prepared by men. Though this has changed somewhat, the representation of men and women as professional chefs is quite different (see below).

Zimmerman’s analysis of food in film has been challenged by anthropologists using the concept of “foodways.” This concept includes both personal and sociopolitical aspects of food, though

the emphasis seems to be on the latter. A book using foodways as an analytical perspective on film claims that the concept “denaturalizes a culture’s norms, values, and beliefs about food products, meal systems, and the procurement, preservation, preparation, presentation, consumption, and cleanup of food” (Baron et al. 2014, “Chap. 1”). Though this analysis of film does not challenge Zimmerman’s claim that there is little eating in films, it focuses more on the sociopolitical aspects of food in film and how these reflect the social and economic structure of food generally. Interestingly, the book referenced above does not use gender in its analysis. However, we can make use of the notion that a gendered analysis of food in film denaturalizes gendered norms. The naturalness of the appearance of food scenes that do not call attention to the food, or the eating, allows us to examine them for the gendered norms that make them seem “natural.”

Food, Film, and Gender

What food worlds are represented in film? Here, I shall limit my analysis to US films and primarily to popular Hollywood films. According to popular films, women and men inhabit different food worlds: their pleasures in food, their anxieties about food, their intimate relationships with food, and their control of food differ, revealing the way that food, as so much else, is ruled by heteronormativity. Women rarely eat, though they often prepare food. When they do eat, they typically eat tiny amounts of low-fat or low-carb foods, often commenting on their eating. They do not, usually, seem to take pleasure in eating. This kind of eating is called “restrained eating” in medical scholarship. “Restrained eating refers to a persistent pattern of eating-related cognitions and behaviours in order to reduce or to maintain body weight” (Macht 2008, p. 2). It appears that, generally, women in film are restrained eaters, with all that that implies about their food worlds. Of course, there are exceptions, but such women are defeminized or represented as psychologically unstable. For example, the independent film *Disfigured* portrays an anorectic woman and an overweight woman, both of whom are psychologically troubled (2008).

The restraint of women eaters, especially at restaurants, is often remarked on negatively in comedies. One example of this is in the hit US film *Shallow Hal* (2001). The film stars Jack Black, a popular lead in Hollywood comedies. Black's body does not correspond to the typical Hollywood male romantic lead, though the range of such bodies is broader than for female stars. He is shorter than most, and stockier. He is not lean and muscled. In this film, he and a friend, played by actor Jason Alexander, who is also short and stocky, are hypercritical of the bodies of the women they are interested in. This is supposed to be amusing, since they are not supposed to be such prizes themselves, but their hypercriticism mirrors the way that many women evaluate their own bodies and the bodies of other women.

Hal meets a positive-thinking guru in an elevator, and the man puts a spell on him that makes him see the "inner beauty" of people. He is promised that the women he likes and finds attractive will also like him. What follows is supposed to be a critique of "lookism" and a hypercritical attitude to the appearance of women. Hal is shown dancing with beautiful, model-thin women. When we are shown the women from his friend's perspective – the non-magical perspective – we see that they do not meet his hypercritical requirements for female beauty. He meets a woman named Rosemary Shanahan, played by Gwyneth Paltrow, and they begin to date. At a restaurant, Rosemary orders a cheeseburger, chili fries with cheese, and a milkshake. And then we hear a variation on one of the most common lines in films about women ordering in restaurants:

Hal: It's nice to see a girl order a real meal. I can't stand it when you guys order a glass of water and a crouton. It ruins the whole point of going out.

When we see Rosemary from an "objective" perspective, she is very overweight. One of the most offensive parts of the film is when Rosemary, who, remember, has "inner beauty" – she has been in the Peace Corps – takes Hal to a hospital where she volunteers with children. He sees the children as healthy and whole. He treats them as such and they have a great time. Eventually, the spell is removed, and Hal sees Rosemary's body as it

really is. He agrees to marry her anyway and go with her into the Peace Corps.

If the film is a critique of "lookism," it undermines itself by portraying the people that Hal sees as beautiful, perfect, and healthy as "normal," while their true appearance is contrasted as not conventionally beautiful and certainly not perfect. This happens with the women he dances with and then when he returns to the children's ward of the hospital and sees the injuries and effects of illness on the children. He is shocked and put off. It is also offensive in that it splits women into two groups: pretty, or not pretty, but funny, smart, and nice. So women can only be unattractive, good people, or attractive, bad people. Never is there any suggestion that Hal might not have a "normal" male body.

According to content analysis studies of films that earned more than \$250 million outside the United States between 1990 and 2007, the most common scenes of men and food involve men using eating or drinking to "share news or information or make plans" (Parasecoli 2009, p. 141). Very commonly, a woman is serving the food or drink. Men do not spend much time worrying about the type of food they eat, or its quality. Of course, these are men of action, not gourmets. But they represent the common heteromascularity seen and imitated around the world. This is the food world of ordinary guys and of lean, muscular men of action.

Both men and women are portrayed as chefs or bakers in films. However, the ways in which they are portrayed are quite different. In *Mostly Martha* (2001) and its US remake, *No Reservations*, a female chef in a restaurant is a perfectionist, obsessive about controlling her kitchen and the food she creates. Her boss requires her to go to an analyst because of her reactions to restaurant patrons who send their food back to the kitchen. She is "fixed," not by the analyst, but by inheriting her sister's child and by working with a male chef who is more emotional and sensual and eventually works his way into her life. Once she has sex, has a man, and has a child, she is a better cook and a better person. In other words, she is "feminized." Interestingly, in the German version of this film, the male chef is Italian, making use of

stereotypical conceptions of the Latin lover and the sensuality of Italian cooking as opposed to French or German nouvelle cuisine. In films, women who cook professionally are masculinized and unstable; they must be brought into the heteronormative fold to become “normal.”

A number of films about women who make food professionally involve the presence of magic in their food. They change other people's lives, always by infusing love, passion, and emotion. They do not seem to be able to do the same for themselves. Their fulfillment is in helping others. Examples include *The Mistress of Spices* (2005), *Chocolat* (2000), *Woman on Top* (2000), *The Recipe* (2010), *Like Water for Chocolate* (1992), and *Simply Irresistible* (1999).

Male chefs who are uninspired or otherwise lacking are often made whole by a return to their ethnic roots. For example, in *Today's Special* (2009), Samir is a classically trained chef whose food lacks inspiration, passion. It is “correct.” To get the passion he lacks, he returns to his father's Indian restaurant, where an itinerant Indian immigrant taxi driver, who used to be a chef in Mumbai (among other things), provides Samir what he needs to find his inspiration in a combination of French and Indian food. In a man's case, it is a return to the ethnic family roots that gives him back the passion he needs to make truly inspired food.

When men are the makers of food, their ethnicity is often emphasized. Ang Lee's *Eat, Drink, Man, Woman* (1994) and the US remake, *Tortilla Soup* (2001), feature families without mothers and fathers who are professional chefs. In both films, the fathers are losing their sense of taste, even as they continue to prepare huge, complex meals of their respective ethnic traditions for their daughters. The fathers use their elaborate meals to try to hold on to their daughters, who are adults and are moving away, into their own lives. The loss of the sense of taste is a symbol of loss of self. The fathers are confused, losing the lives they have lived, unsure of how to move to the next stage of life, how to renegotiate their relationships with their daughters and others.

Interestingly, it is when a daughter takes up the father's expertise and cooks for her father that the

men regain their sense of taste – like magic. So, once again, women are sensually connected with food. As in the films mentioned above, they imbue their creations with love, which acts on the loved ones to return sensuality and enjoyment – pleasure in the senses or joy itself.

According to popular films, women stop being reticent eaters only when they know they are going to die. Queen Latifah, as Georgia in *Last Holiday* (2006), makes exquisite meals following TV food programs, but only eats Lean Cuisine meals. She gives away the food she makes. She is also pleasure denying to herself in other ways. In the film, Georgia receives a diagnosis giving her just a few weeks to live. She takes all of her money and goes to a hotel in the mountains in Europe where one of her favorite chefs heads the kitchen. At dinner the first night, we see guests ordering food, but asking that certain ingredients be omitted. For example, one guest, a woman, asks whether they can make “the risotto without the dairy.” As he receives these orders, the chef throws a fit, as people want his dishes with no fat, no this, no that. Georgia, however, orders everything on the menu just as it is described, and the chef is so delighted that he comes to meet her. She continues to eat rich, beautiful food, but only because she believes she is going to die. Her changed attitude toward the pleasures of eating is not resolved at the end of the film, when she learns that the diagnosis was incorrect, and she will not die any time soon.

In *Seeking a Friend for the End of the World* (2012), earthlings have just learned that the last attempt to save the earth from an asteroid has failed and that everyone will die in 2 weeks. At a dinner party, guests are asked how they will spend the remaining days of their lives. A single woman – portrayed as silly and vapid – says that one of the things she will do is “eat whatever I want, and not even care.” This speaks volumes about her food world and that of many other women.

The gendered norms regarding food are largely true of norms about sex in film. In mainstream films, women are not supposed to desire sex, or to exhibit that desire, except under certain very specific conditions. Interestingly, when women eat like men and approach sex as men do, they are

masculinized, and the two – food and sex – usually go together. In *La Femme Nikita* (1990) and its US remake, *Point of No Return* (1993), Nikita, a killer who is offered her freedom if she agrees to become an assassin for the government, eats heartily, stuffing her face, shocking the man invited to share her meal. The meal is followed by an aggressive sexual overture, another sign of her masculinity. The man says that he is used to making the invitation, but goes along. The effect is to feminize him and masculinize her. She is, after all, a trained assassin. In her training to be an agent, she has been explicitly schooled in femininity, in the French film by Jeanne Moreau. Part of that training is learning how to eat – in public.

The close relationship between women's repression of appetites generally – eating and sex in particular – is evident in film portrayals of female vampires. They become masculine in their appetites. They feed voraciously, and they are sexually aggressive as well. Male vampires are also, but their predatory behavior, both sexual and food related, is not of a different kind from their ordinary masculine behavior, though many vampires are depicted as bisexual, which, for some, threatens their masculinity. Vampire women feed and feed, have sex with everyone, and never get fat or pregnant. They are not restrained eaters.

Summary

Though there is not much eating in films, what eating there is and the role of food in films reflect gendered food worlds. The identification of women with the body and appetites, and the responsibility of women to control those appetites, both for themselves and for men, is commonly portrayed in films. Women in films are “restrained eaters.” When they are not, they are depicted as masculinized and often as psychologically unstable. Women may cease to be restrained eaters when death is near. Men, on the other hand, eat whatever is available and eat as much as they want. The heterosexual food world for men in Hollywood films is one where eating is necessary, like refueling, but not worth much thought. Men are rarely the preparers or providers of the food they eat.

When men do think about food, they are either professional chefs or not heterosexual. Rock Hudson's famous scene with Doris Day in *Pillow Talk* is a classic example of the latter. He is trying to make her uninterested in him, so he starts acting “gay”; one of the ways in which he does this is to show excessive interest in a recipe for a dip. Even today, in films, such codes are used, often still for comic effect.

Films in which men and women are chefs differ significantly. Women who are singularly focused on their craft are portrayed as masculine and as therefore abnormal. They must be re-feminized by male lovers, children, or nurturing. Male chefs are not feminized by their cooking, because being a chef is a traditionally masculine role. When male chefs lack passion in their craft, they get inspiration not from romantic love, but by returning to their ethnicity, often by way of their fathers, or by passing on their profession to their child, acting as the *pater familias*.

The relationships between eating, types of food, relationships to food, and gender in the movies reflect those of cultures at large. In film, as in life, food worlds are gendered.

Food, Agriculture, and Trade Organizations

Carmen Bain

Department of Sociology, Iowa State University,
Ames, IA, USA

Synonyms

Trade associations; Trade institutions; Trade groups

Introduction

Trade organizations establish and enforce the rules of trade. The exemplary example of such an organization is the World Trade Organization (WTO). Established in 1995, the WTO marked the first time that an international organization had the legal mandate to regulate trade between nations, a role previously under the purview of individual nations. The objective of the WTO is to replace national trade rules, such as tariffs and quotas, and prohibit nontariff trade barriers, such as technical barriers or rules of origin, with a single institutional framework designed to allow trade to flow “as smoothly, predictably, and freely as possible” (World Trade Organization 2013). Changes wrought by the WTO led to the deepening of market relations globally, including the expansion of global value chains (GVC), where production is integrated from start to finish (Busch and Bain 2004; Bair 2009). Here, large-scale corporations, such as a Walmart, source a significant proportion of their product from thousands of different suppliers around the globe. The development of the WTO and GVC has had two significant effects on trade: first, it has led to a massive expansion in global trade in food and

agricultural products, and second, corporations themselves have emerged as important trade organizations, establishing and enforcing rules to regulate the trade within their value chains.

The shift in global rule setting and the concomitant expansion in global trade gave rise to a number of ethical concerns. In particular, the WTO and large-scale corporations became the target of antiglobalization critics who argued that these organizations favor enforceable rules that encourage global market expansion, while rules that promote social goals, such as human rights, environmental sustainability, and labor standards, were largely absent (Ruggie 2003). Critics argued that as a result, inequality and injustice both within and between countries is exacerbated due to the combined effects of, first, market integration globally that constrains the ability of nation-states to function and to regulate trade and, second, the growing dominance of organizations, such as the WTO, that advocate economic rather than social objectives (Little 2003). In other words, liberalized trade rules facilitated the mobility of capital and goods, but equivalent rules that could adequately regulate the negative consequences of international trade were absent (Clapp and Fuchs 2009).

Within this context, many nongovernmental organizations (NGOs) concluded that traditional campaigns for social, economic, and environmental justice and equity were no longer effective. Recognizing the weakened role of the nation-state in policing international trade, many NGOs turned their attention instead to try and change the practices and policies of those actors they held responsible: corporations (Ruggie 2003). Through campaigns for corporate social responsibility (CSR), the goal of NGOs was to compel individual companies to integrate rules and policies into their production and trading practices that would address social, economic, and environmental concerns. This strategy has proved remarkably successful at encouraging corporations to do so.

A useful concept for considering the ethical issues involved in global trade is governance. In contrast to government (legislative, executive, judicial)-centered analyses of regulation, scholars

are increasingly interested in emphasizing transnational governance structures (Gary Gereffi 2005). Scholars use the concept of governance to investigate the multiple actors, sites, and forms of governing that regulate the global agrifood sector (Higgins and Lawrence 2005, p. 13) and to consider its social, political, and ethical implications. Scholars who utilize this concept are particularly interested in considering how the regulatory boundaries between the state, market, and civil society have blurred and to analyze the development and role of novel actors and contexts through which governing occurs (such as global value chains, business and industry associations, or multi-stakeholder-led initiatives (MSIs)) (Higgins and Lawrence 2005; Smith and Mahutga 2009).

Governance structures and practices within global agrifood chains create a division of labor that effects how resources, as well as costs, risks, and rewards, are distributed among actors (Ponte and Gibbon 2005). From an ethical standpoint, therefore, a focus on governance is useful for understanding relationships of power and inequality within the agrifood sector including the distributional effects of global value chains (Ransom 2007; Bain 2010b; Prieto-Carrón and Lerner 2010) and for helping to reveal the social relations bound up in the production of commodities (Guthman 2009). To accomplish this, governance scholars focus analytical attention on how actors and organizations use their power and authority to shape this division of labor within value chains as well as the tools, techniques, and activities, such as standards and audits, that they use to influence and coordinate the production, exchange, and consumption of food and agricultural products (Higgins and Lerner 2010; Tallontire et al. 2011).

This entry examines two new nongovernmental organizational forms that have emerged to regulate trade and which explicitly seek to embody rules to advance socially responsible and ethical trade. The first example is the food retailer initiative, GLOBALG.A.P., and the second example is that of multi-stakeholder-led initiatives (MSIs) or “roundtables.” I discuss governance efforts by these organizations to develop standards and auditing systems that incorporate rules to address the social, economic, and

environmental performance of corporations within the global marketplace. The entry then outlines some of the major ethical concerns that have emerged from these developments.

Historical Development of Trade Organizations

After World War II, international trade in food and agricultural products was limited by national tariffs, quotas, and a host of nontariff trade barriers, such as sanitary and phytosanitary measures, designed to protect domestic industries and agricultural sectors. The WTO's mandate was to devise rules for international trade that would facilitate global trade by reducing and even eliminating trade barriers. The WTO has international legal status with enforcement powers similar to the United Nations (UN), and its rules are binding on member states. Initially, the goal was to reduce and phase out tariffs and quotas. However, as states began to recognize that a proliferation in nontariff trade barriers could threaten the system, attention was turned to developing a series of subsidiary agreements. These agreements restrict the use of nontariff trade barriers through the establishment of consistent, harmonized, and transparent standards based on scientific principles and evidence, which are enforceable (Busch and Bain 2004). For example, the Sanitary and Phytosanitary (SPS) agreement established rules for meeting standards for food safety and animal and plant health that do not function as a trade barrier. To ensure that standards do not act as a trade barrier, the WTO expects individual countries to base their standards on those established by the Codex Alimentarius Commission (Codex), the World Organization for Animal Health (OIE), and the Secretariat of the International Plant Protection Convention (IPPC).

The liberalization of global rules on trade had a profound effect on market relations globally. Of particular significance was the expansion of global commodity or value chains. Rather than international, business-to-business, or the use of spot markets, trade is increasingly organized through value chains where production is

integrated from start to finish at a regional or even global scale (Bair 2009). Scholars involved in global value chain analysis (GVCA) emphasize the importance of global buyers, especially retailers and brand-name companies, as key organizations in the formation and regulation of global production, trade, and marketing (Gereffi et al. 1994; Bair 2009). These scholars argue that GVC are increasingly “buyer driven” rather than “producer driven.” In buyer-driven value chains, lead firms, such as retailers, play a central role in making and enforcing decisions about practices and structures in the global economy, even though they do not own any of the production or manufacturing facilities themselves.

Today, for example, large-scale retailers, such as Walmart or Tesco, directly source a significant proportion of their product especially fruits and vegetables from thousands of different suppliers around the globe. To ensure consistent quality (e.g., food safety) and quantity (year-round supply) of product within their value chain, retailers are directly engaged with governing their value chains, especially through the use of standards and third-party certification, thereby shaping the conditions under which food and agricultural products are produced and traded globally.

Corporate Social Responsibility

Concerns regarding the ethics of corporate behavior are especially pertinent within the agrifood sector since the sector arguably represents the convergence of human rights, animal rights, and community and environmental issues more than any sector. As supermarkets have globalized, their supply chains have become increasingly complex while at the same time demands by stakeholder communities have become more challenging to meet. This sector has to deal with concerns not only about food safety but also regarding environmental hazards, genetically modified organisms, the use of pesticides, child and forced labor, health and welfare issues related to agricultural laborers, and animal welfare (Barrientos and Dolan 2006).

NGOs have questioned the social and environmental impacts of global food production in a

context where the capacity of individual nation-states to regulate trade as well as to govern public goods, such as food safety or worker welfare, within this trade has diminished (Barrientos and Dolan 2006, p. 4). Instead, many NGOs have turned their attention to campaigns for CSR with the goal of advancing their social, ethical, and environmental objectives by compelling individual companies to change their production and trade practices wherever they happen to operate within the global marketplace. Today, the dominant philosophical belief is that in the era of globalization, it is the corporate sector that has “the global reach and capacity” as well as the “ability to make and implement decisions at a pace that neither government nor intergovernmental agencies can possibly match” (Ruggie 2003, p. 107).

It is important to note that there is no single, coherent definition of CSR and the vagueness of the concept has allowed it to be interpreted and adopted by different actors for different purposes (Blowfield and George 2005). Blowfield and George (2005, p. 503) argue that it is better to think of CSR as a concept that incorporates a range of theories and practice, which all recognize the following:

(a) that companies have a responsibility for their impact on society and the natural environment, sometimes beyond legal compliance and the liability of individuals; (b) that companies have a responsibility for the behaviour of others with whom they do business (e.g. within supply chains); and (c) that business needs to manage its relationship with wider society, whether for reasons of commercial viability or to add value to society.

Nor are NGO campaigns for CSR homogeneous. Rather, the strategies and goals tend to reflect the particular ideological perspective of the organization involved.

One of the most effective approaches early on was to publicly shame and stigmatize corporations into changing their behavior by publicizing cases of malpractice within their supply chains. These early campaigns were inspired by a number of high-profile social and environmental catastrophes in the mid-1990s including the toxic leak at a Union Carbide pesticide factory in Bhopal, India;

the *Exxon Valdez* oil spill in Alaska; Shell Oil operations in Nigeria; the spread of genetically modified (GM) food and agricultural crops; continued tropical deforestation; and exposés of sweatshop labor by major branded corporations, such as Nike and Gap (Utting 2005). Working on the idea that “high-profile brand-name corporations can run but they cannot hide” (Utting 2005, p. 380), these campaigns target highly visible, reputation-sensitive, corporate brands at the retail end of the supply chain, those with direct links to consumers. By focusing on brand names with high visibility or symbolic value, such as McDonalds, Starbucks, or Walmart, campaigns are more likely to attract media interest and resonate with the wider public (Bendell 2005; O’Rourke 2005). Below, I discuss two examples of CSR.

Business-Sector-Led Initiatives

Food retailing has become increasingly concentrated, resulting in a handful of major supermarkets in Western Europe, the UK, and the USA, wielding enormous power and influence in determining how food is produced, traded, and consumed (Campbell et al. 2006; Lawrence and Burch 2007; Vorley 2007). Ironically, the reliance by these retailers on centralized procurement systems has increased their vulnerability to activist and media campaigns spotlighting unethical practices within their global value chains (Barrientos and Dolan 2006; Konefal et al. 2007). Food retailers have found that their valuable brands can be severely damaged if they are linked with unethical practices, such as child labor, destructive environmental practices, or genetically modified organisms. Furthermore, public concerns about the ethics or safety of the food system – whether real or perceived – have the potential to negatively affect the entire industry, not just the firm or producers responsible. Ignoring social and environmental problems, and failure to demonstrate due diligence in finding or preventing such problems, can pose considerable reputational and financial risks not simply to an individual retailer but the industry as a whole.

To address this, retailers seek to control their global supply chains by incorporating

requirements for CSR that suppliers are obliged to meet if they wish to participate in the global marketplace (Barrientos and Dolan 2006). Retailers use institutions, such as standards and third-party certification, in addition to other criteria to determine what products get traded, which producers can participate in the value chain, and under what conditions. For example, Walmart has developed its “Live Better” campaign as part of its global responsibility initiative, which includes standards to ensure ethical sourcing within its global supply chains. UK food giant, Tesco, has its “Nurture” program that sets standards for Good Agricultural Practices, including rules regarding the environment and worker welfare.

From the perspective of corporations, voluntary self-regulation is preferable to control by the state and many businesses value CSR initiatives as a means of protecting their brand-name reputation and managing economic risk. Voluntarist approaches to regulate corporate behavior within the global agrifood system have also garnered support from governments, especially in the UK and Western Europe, and among international organizations, such as the European Union (EU) and the United Nations (UN).

A preeminent example is GLOBALG.A.P., a consortium of major food retailers who created and implemented a set of agrifood standards to govern trade within their value chains. Launched in 2001, GLOBALG.A.P. (called EurepGAP until 2007) was conceived by a group of supermarkets from the UK and Europe who were concerned with establishing a set of harmonized, independently verified standards intended to address public concerns about food safety, environmental impacts, and the health, safety, and welfare of workers and animals. The basis for collaboration reflected the desire by GLOBALG.A.P.’s founders to avoid a situation where each company was engaged with developing its own standards and auditing system. Not only would this prove enormously expensive and time-consuming but company-based standards could make it difficult to sustain guaranteed supplies of certified product from producers.

These retailers recognized that they had a common interest in creating a harmonized set of requirements that would facilitate global trade within their supply chains by ensuring that supplies were interchangeable between companies (Bain 2010a). The intent was that GLOBALG.A.P. would function as a baseline standard with individual companies then free to develop additional standards and audit schemes (e.g., Tesco’s Nurture) if they wished to do so.

The protocol was originally focused on fresh fruit and vegetable suppliers but has since expanded into other crops (including coffee, tea, and flowers), livestock, and aquaculture. To participate in GLOBALG.A.P., producers are required to meet a broad array of food safety and quality standards as well as labor and environmental standards and, in the livestock sector, animal welfare standards. To demonstrate compliance, producers must be independently audited by a third-party certifier who is approved by GLOBALG.A.P. While these standards are not mandated by law and thus considered voluntary, the reality is that compliance with GLOBALG.A.P. has essentially become an “entry ticket” for trading within the UK and EU marketplace (Campbell et al. 2006; Fox and Vorley 2006). Consequently, producer participation in GLOBALG.A.P. has continued to grow since 2001 with GLOBALG.A.P. establishing itself as the world’s leading farm assurance program with some 130,000 producers from more than 110 countries certified in over 400 products (International Trade Centre 2013).

Multi-stakeholder-Led Initiatives

Business-led efforts to incorporate standards and codes of conduct for CSR within their trading relations have been significant. Yet, many proponents of CSR remained concerned about the lack of accountability, transparency, and participation within such efforts. Subsequently, in recent years, one of the most significant trends intended to enhance “stakeholder dialogue, participation, and partnership” (Bendell 2005, p. 362) within global value chains is multi-stakeholder-led initiatives (MSIs) or “roundtables” where a range of stakeholders concerned about the same issues sit down at the same table (Bailis and Baka 2011;

German et al. 2011; Partzsch 2011). With MSI, nongovernmental organizations (NGOs) collaborate with businesses to develop company codes of conduct, labor and environmental standards, and auditing systems designed to improve business practices within the global trading environment (O'Rourke 2005; Djama et al. 2011; Levidow 2013).

Proponents argue that since MSI are more inclusive than business-led initiatives, a broader range of interests and concerns can be addressed (Schouten and Glasbergen 2011). Many large-scale corporations are motivated to participate in these novel organizations as a means of harmonizing their global standards and establishing their public credibility as socially responsible, thereby minimizing social and economic risk (Ponte and Cheyns 2013). Examples of MSI within the agrifood sector include the Marine Stewardship Council's (MSC) Sustainable Fishing Programs, the Rainforest Alliance Certified Programs, and the UK's Ethical Trade Initiative (ETI).

Significantly, MSIs have flourished in the biofuels sector where the expansion in global trade in biofuels and the establishment of MSI have developed almost hand in hand. The rapid expansion in the production of biomass crops such as corn, palm, soy, and sugar in developing countries to produce biofuels, especially for the European market, has raised a number of complex ethical issues concerning food security, land grabs, water grabs, deforestation, loss of biodiversity, labor rights, and greenhouse gas (GHG) emissions (Selfa et al. [forthcoming](#)).

The establishment of the EU's Renewable Energy Directive (RED) in 2009 provided impetus to many MSIs. The RED includes several environmental sustainability criteria; however, its major focus is that 20% of all energy and 10% of transportation fuels will come from renewable sources by 2020 and that an initial 35% GHG reduction will increase to 60% for new biofuel installations by 2017 (Bailis and Baka 2011; Levidow 2013). In 2012, EU member states approved seven nongovernmental standards and certification schemes created to ensure that biofuels traded within the EU meet the RED sustainability rules, including the MSI's Roundtable

on Responsible Soy (RTRS), the Roundtable on Sustainable Palm Oil (RSPO), and Bonsucro.

For example, Bonsucro is a MSI that has developed sustainability standards and certification for sugar and sugarcane ethanol production. Bonsucro's membership includes NGOs (e.g., the World Wildlife Fund and Solidaridad), sugarcane producers and ethanol production companies, and end-user companies, such as BP and Shell. Bonsucro excludes governments from its organization, which is the norm among MSIs (Ponte 2008; Cheyns 2011). Bonsucro explains on its website that its standards and certification will ensure "that a farmer sees better yields, human rights are respected, the planet benefits from better stewardship, the miller becomes more efficient, the trader gains more visibility, the end user greater transparency of origin, and we all...benefit from knowing that Bonsucro certified means 'sustainable'" (cited in Selfa et al. [forthcoming](#)).

Establishing Legitimacy

Despite efforts to incorporate CSR, the growing role of business, business associations, and MSI in determining the organization and rules of trade continues to pose important ethical concerns and dilemmas related to trade. One concern is the challenge that these organizations pose for democratic systems of government (Bendell 2005). Within this context, scholars have become increasingly interested in how such organizations establish legitimacy. Legitimacy is concerned with normative aspects of authority, who is understood to have the authority or right to rule and who is obligated (but willing) to obey that rule (Partzsch 2011).

Within liberal democracies, the state's authority to rule, and the willingness of its citizens to accept that rule, is derived from democratic norms (e.g., elections) whereby citizens can hold representatives accountable for their performance (Partzsch 2011). The challenge for non-state actors is how to gain approval from different stakeholder groups in society since rules imposed through the use of market power are vulnerable to challenge as undemocratic and therefore

illegitimate (Clapp and Fuchs 2009; Higgins and Lerner 2010).

Discursive and communication practices are mechanisms through which organizations attempt to establish legitimacy (Gibbon and Ponte 2008; Clapp and Fuchs 2009; Higgins and Lerner 2010). Of particular interest to scholars is the importance of organizations appealing to technoscientific norms and values (Konefal and Hatanaka 2011) and “expert knowledge and practice” (Gibbon and Ponte 2008, p. 366). Here, organizations assert that institutions such as standards should be based on technoscientific values such as objectivity and value freedom with rules of measurement that are quantifiable and scientific. In other words, a good standard should incorporate rules of measurement, which become the means through which standards can be quantified (Bain et al. 2010).

For example, Bonsucro conveys the idea that its legitimacy is premised on its use of scientific standards that are politically independent from the government. Bonsucro explains that it has developed a “global metric standard” based on a “set of metric measurements” designed to measure the sustainability of sugarcane and its impact. Bonsucro frames its standard as superior to government regulation because it is scientific, nonpolitical, and value neutral (Selfa et al. forthcoming).

To help establish legitimacy for its standards, GLOBALG.A.P. emphasizes that its standards are based upon technoscientific principles, such as risk assessment, which are independently verified by accredited third-party certifiers. For example, GLOBALG.A.P. argues that its “protocol has been developed by experts and is heavily risk assessed. By adhering to good agricultural practice we reduce the risk and there are a number of other significant benefits with respect to worker safety and welfare. To achieve [our] goals, [GLOBALG.A.P.] seeks to achieve global consistency in their standards by verifying best practice objectively” (cited in Bain 2010a).

In addition, GLOBALG.A.P. emphasizes its use of risk assessment to discern just how rigorous its standards need to be. For example, in 2007, GLOBALG.A.P. developed a module to address

high-risk instances of worker health, safety, and welfare known as “Good, Risk-Based Agricultural Social Practice” (GRASP). This module is separate from the GLOBALG.A.P. general protocol and is only intended as a voluntary standard that retailers can demand for regions of the world or sectors of the industry where the “risk of social misbehavior” is higher (GLOBALG.A.P. et al. 2007, p. 6). In not requiring this module for all workers, GLOBALG.A.P. argues that mainstream agriculture cannot afford to implement broad-based labor standards or full social audits (GLOBALG.A.P. et al. 2007). Rather, it argues that rigorous labor standards and social audits are only realistic and affordable in niche markets where consumers are willing to pay (e.g., Fair Trade or the Ethical Trading Initiative (ETI)) or where the risk of a problem is especially high (e.g., GRASP) (GLOBALG.A.P. et al. 2007).

To gain legitimacy, the rules established by private-sector trade organizations must be accompanied by a system of oversight that is perceived as independent, transparent, and expert based (Hatanaka et al. 2005; Campbell et al. 2006; Campbell and Le Heron 2007). Within the global agri-food system, third-party certification (TPC) is understood to embody such practices and norms, and TPC has emerged as one of the primary mechanisms through which organizations attempt to achieve legitimacy. Third-party certifiers are responsible for assessing, evaluating, and certifying whether a producer has met an agreed-upon set of standards (Hatanaka et al. 2005). TPC then conveys information about specific safety or quality claims of a product (e.g., maximum residue levels for pesticides, good labor practices, or animal welfare) from the producer to the buyer and/or consumers and government regulators.

TPC creates organizational legitimacy based on the assumption that its audits utilize technoscientific expertise and that it provides transparency and accountability to stakeholders and the public (Konefal and Hatanaka 2011). In addition, its independence from producers, buyers, NGOs, or government regulators enhances its broad appeal and authority as objective and impartial since it is viewed as having no stake in the outcome of the audit (Hatanaka et al. 2005). The

certification process, therefore, is presumed to be fair to all participants within the value chain (Bain and Hatanaka 2010).

Technoscience as the Practice of Power and Exclusion

Organizations involved with trade rely on standards and TPC to coordinate and govern the global agrifood system. In the struggle over whose rules should rule, organizations appeal to technoscientific norms and values to legitimize their standards or TPC and thereby assert their authority to govern across industry sectors, nations, and global value chains. However, questions of power are often hidden behind the language of scientific objectivity and value neutrality, and if standards and TPC within the agrifood system are about power, “then they must also be about ethics and justice” (Busch 2011, p. 239).

A growing body of literature suggests that this emphasis on technoscientific values and practices in the standards setting processes, together with the use of TPC, tends to privilege powerful actors and sideline the concerns of less powerful stakeholders, such as small-scale producers and workers, about justice and equity within the global trade system (Tallontire and Vorley 2005; Bain 2010b). It is a means to limit participation by producers and workers in the Global South within the decision-making process (Bain and Hatanaka 2010; Partzsch 2011).

For example, GLOBALG.A.P. emphasizes that “complete social audits with in-depth investigations and worker interviews are NOT in the scope of GRASP,” its third-party audit program for high-risk agrifood chains (GLOBALG.A.P. et al. 2007, p. 3). Studies of the structures and functions of organizations, such as MSI, suggest that despite efforts to make these organizations more participatory and democratic, their emphasis on certain technoscientific values and discourse tends to marginalize “nonexpert” stakeholders, such as workers, small-scale producers, and rural communities, who cannot conform to these discourses (Bain 2010a; Bain and Hatanaka 2010; Cheyns 2011; Ponte and Cheyns 2013). A focus on techno-legal language reinforces existing power relations by discrediting alternative “forms of proof” that communities in the

Global South typically use to provide evidence about, for example, land rights (Silva-Castaneda 2012). Cheyns (2011) found that MSI tend to depoliticize standards by focusing on “strategic engagement” thereby stifling efforts by local communities to debate questions of justice. Similarly, recent work on biofuels has suggested that “the institutional, discursive and symbolic value of sustainability certification” depoliticizes and legitimizes the expansion of monocultural biomass production (e.g., sugarcane, corn, soy, palm plantations) together with its concomitant land and water grabs by elites and “dispossess[ion] of rural communities” (Levidow 2013, p. 211; see also, Schouten and Glasbergen 2011; Selfa et al. forthcoming). In sum, despite claims of CSR, most trade organizations continue to emphasize the technoscientific values within their governance strategies, which are then used “to privilege some actors and forms of knowledge while marginalizing others” (Konefal and Hatanaka 2011, p. 125).

Summary

Corporations, business associations, and MSI have emerged as key players in the regulation of production, trade, and consumption, establishing governance mechanisms, such as standards, codes of conduct, and TPC, designed to regulate people and things within global value chains. Here, scholars are concerned with understanding the role that these organizations play in enhancing – or diminishing – the social, ethical, and environmental performance of business throughout the global agrifood system. Scholars have been particularly concerned with understanding how these organizations create legitimacy by utilizing technoscientific and expert practices and discourse. The governance literature has emphasized that this is an area that is deeply political even while posing “as depoliticized” (Ponte et al. 2011, p. 289). In other words, institutions – norms, rules, conventions, and certification – always unfold within specific political economies and power relations (Ponte 2008; Bain and Hatanaka 2010; Busch 2011; Klooster 2011).

Moving forward, it is important to continue to explore the practices, structures, and forms of asymmetrical power that exist within organizations, including MSI, and the implications of this asymmetry for social and ethical practices (Cheyns and Riisgaard [forthcoming](#)). Moreover, if institutions are inherently political and ethical, then one of the fundamental challenges that remain is how to construct democratic processes that allow us to adjudicate questions of fairness and justice within the agrifood system.

Food, Class Identity, and Gender

S. Margot Finn

[Inequality](#); [Social class](#)

Introduction

“Class” refers to hierarchical divisions in society based on wealth, income, prestige, and/or one’s relationship to the means of economic production (i.e., factory owner or worker, landowner, or peasant). Traditional definitions of class are based primarily on material assets, wage labor, and occupational status; they rarely account for unpaid work or everyday practices like shopping, cooking, and eating. Newer “culturalist” or “pluralist” approaches define class as a socially constructed identity that may depend as much on lifestyle and taste as material assets and labor conditions. Feminist scholars also emphasize the intersections between class identity and other social identity categories like gender, race, ethnicity, sexuality, religion, nationality, age, and ability.

Food plays a central role in the construction of and lived experience of class and gender. This entry explores some of the ethical questions that arise from the relationships between class, gender, and food in five realms: hunger and food access, eating disorders, diet and body size, labor, and cultural capital.

Hunger and Food Access

Class and gender are two of the primary factors that determine whether someone will be affected by hunger. According to the UN Food and Agriculture Organization, the world produces more than enough calories for the current population; nevertheless, approximately 870 million people chronically lack sufficient food for their daily energy requirements (FAO 2012). The overwhelming majority (852 million) live in the developing world and occupy the lowest social stratum, lacking the resources to produce enough food on their own or buy the food available in markets. Temporary food shortages caused by weather, conflict, and distribution problems also primarily affect the poor.

The UN estimates that 60% of chronically hungry people are women or girls. Worldwide, women own fewer and less productive agricultural resources and have less purchasing power than men. In some countries, tradition dictates that women eat last, which means they eat less than men when food is scarce and eat a less varied diet with fewer nutrient-dense foods like meat and vegetables. Women are also more likely to go without food during temporary shortages while men and boys get what little food is available. For all of these reasons, women and girls are more likely than men and boys to suffer from problems associated with malnutrition, including diminished learning and work capacity, increased susceptibility to infection, and stunted growth. Malnutrition also puts women at greater risk of death during pregnancy and childbirth (Committee on World Food Security 2011).

Chronic hunger primarily affects people in developing countries, but even in developed countries some people lack reliable access to

sufficient food. In the USA, approximately 15% of households were classified as food insecure in 2011, meaning they had difficulty providing enough food for all their members all the time, and 5.7% were very food insecure, meaning food intake was reduced and meals were skipped due to a lack of resources. Rates of food insecurity are higher for households with children headed by a single woman (25.3% food insecure; 11.5% very food insecure) and women living alone (7.7% food insecure; 7.9% very food insecure) (ERS). As with chronic hunger, food insecurity usually occurs in the presence of available food that people simply cannot afford to purchase; however access to food may also be a factor. The term “food desert” was developed in the 1990s to refer to neighborhoods with few food markets and limited transportation options. Whether or not these neighborhoods truly lack adequate food is contested; however, there is broad agreement that disparities in the retail food environment of developed countries correspond to disparities in neighborhood income levels and that poorer people often have less access to some types of food, particularly fresh produce.

Eliminating hunger is widely recognized as an urgent humanitarian need and an issue of social justice. In addition to the suffering hunger causes directly, malnutrition also helps perpetuate poverty. Due to the disproportionate affect hunger has on women, alleviating hunger is also an issue of gender equality. The right to adequate food is enshrined in international human rights law, including Article 25 of the 1948 United Nations *Universal Declaration of Human Rights*, which declares every person’s right to “a standard of living adequate for the health and well-being of himself and of his family, including food, clothing, housing, and medical care.” The USA has historically opposed formal recognition of the “right to food,” and at the 2002 World Food Summit, representatives from the USA argued that the right to food should mean “an opportunity to secure food and not a guaranteed entitlement” (Butterly and Shepherd 2010).

Even among those who agree that the right to food should be a guaranteed entitlement, there is considerable debate over who is responsible for

feeding the hungry, whether charity creates dependency instead of self-sufficiency, and how to handle situations where food aid might undermine national or cultural sovereignty. For example, the international community was reluctant to intervene in the rural famine in Ethiopia in 1973–1974 in part because the country’s regent, Haile Selassie, said he did not want his country to look like “just another starving African nation” in need of large-scale emergency aid operations while they were hosting the tenth anniversary of the Organization of African Unity. Educating girls and women and offering women microloans to start small businesses have been shown to reduce malnutrition and improve their community’s food security; however, targeting women often involves violating their societies’ preferences. Selecting girls and women for special education and empowerment programs may put them at risk of retaliation.

There are also ethical questions raised by the use of food aid as a political instrument and the practice of attaching conditions to aid. The USA has been criticized for its decision to send food aid to the Eritrean separatists in Ethiopia in 1985, which was interpreted as an attempt to stoke the continuing civil war and topple the Soviet-allied Mengistu government. The World Food Programme struggled with the question of conditions in its efforts to address food shortages in Zimbabwe in the 2000s. President Robert Mugabe only wanted food aid distributed to those who supported his government, which was widely seen as the primary cause of the shortages. Some argue that attaching conditions to aid is inherently immoral, but without conditions, food aid may not reach those who need it most or may be used to prop up tyrannical governments (Butterly and Shepherd 2010).

Eating Disorders

Abnormal eating patterns involving restricted or excessive consumption are generally believed to be most prevalent in white middle- and upper-class women in North America and Western Europe; however, they also appear to be

increasing around the world. The three most widely recognized and studied eating disorders are anorexia nervosa, bulimia, and binge eating disorder [BED]. Anorexia nervosa is usually characterized as the relentless pursuit of thinness through refusing or restricting food. Bulimia is characterized by episodes of bingeing, or eating large amounts of food, followed by purging, usually by inducing vomiting or using diuretics and laxatives. Binge eating disorder [BED] resembles bulimia, but typically without purging. Other eating disorders include purging disorder (bulimia without bingeing episodes), diabulimia or the manipulation of insulin by diabetics to bring down their weight, night eating syndrome, and orthorexia or an obsessive concern with food purity. Eating disorders are often accompanied by a fear of fat and body dysmorphic disorder, or a distorted self-image usually characterized by feeling fat despite appearing thin to others.

Eating disorders are both an immediate cause of suffering and can lead to other health problems, a diminished life, and sometimes death. Approximately 15% of anorexics die from suicide or starvation. Like hunger, eating disorders make people more susceptible to other diseases and reduce their capacity to learn and work. Eating disorders are also associated with depression and substance abuse. There are ethical questions raised by some treatment and prevention strategies and the possibility that contemporary understandings of the disorders may exclude marginalized groups.

Most researchers believe that eating disorders are caused by an interaction between biological, psychological, social, and cultural factors. Joan Jacobs Brumberg argues that the emergence of anorexia in late nineteenth century England and America was facilitated by the fashion for fragility and sickness in bourgeois women, the association between eating (especially meat) and sexual desire, and tensions in the Victorian nuclear family particularly around the socialization of adolescent girls (Brumberg 1988). Contemporary eating disorders are often linked to the intensification of public concern about obesity since the 1980s and the aesthetic preference for thinness represented by cultural products like Barbie and

the unrepresentative thinness of most women portrayed in mass media and fashion. The prevalence among white and Asian girls in the middle and upper classes may reflect the particular pressure many in that demographic feel to adhere to dominant beauty ideals.

However, the widespread association of eating disorders with wealthy, white adolescent females may also be both a result and cause of underdiagnosis in other groups. Men and boys might be less likely to seek treatment for symptoms associated with a feminized condition. Additionally, men and older women appear to be more likely to suffer from BED, which has only recently attracted the attention and concern of researchers and doctors. According to one survey of adults in the USA, 0.9% of women and 0.3% of men reported having anorexia at some time in their lives, 1.5% of women and 0.5% of men reported having bulimia, and 3.5% of women and 2% of men reported having BED (Hudson et al. 2006).

The focus on middle-class white adolescent girls' experience of eating disorders may also have shaped the way the disorders are defined and understood in ways that exclude the particularities of how they manifest in other populations. In Becky Wangsgaard Thompson's interviews with nonwhite, poor, and lesbian women with eating disorders, many of them described bingeing in order to achieve a numbed mental state similar to drunkenness or a drug high. Other interview subjects reported wanting to alter their bodies after an assault, either in an attempt to return to a childlike thinness they hoped would attract less unwanted sexual attention or to achieve a kind of sexual invisibility through fatness. Thompson argues that the dominant approach to eating disorders has underestimated how often they arise in response to racism, sexual abuse, poverty, sexism, emotional and physical abuse, heterosexism, and classism, all of which are more likely to affect people outside the demographics traditionally seen as most at risk (Thompson 2002).

There is considerable debate and little consensus about what treatment strategies are most effective. Anorexic patients who reach a very low weight are traditionally hospitalized and sometimes fed via tube or IV against their wishes. In

an alternative called the Maudsley approach, patients remain at home where their feeding is supervised by family members. Critics of the Maudsley approach claim that family members, especially the parents of adolescents, should remain removed from treatment to preserve the patients' privacy and autonomy (Brown 2006). Treatments are often expensive and many health insurance plans provide little or no coverage, effectively restricting access to the full range of possible treatments to the rich.

Some people with eating disorders argue that all forms of treatment are inappropriate violations of their autonomy. Participants in pro-ana communities, which often take the form of online message boards and groups on social networking sites, claim that they are not diseased and that their "symptoms" are accomplishments of self-control and central to their identity. Some medical associations and advocacy groups have asked that pro-ana sites be shut down because they encourage self-harm. Yahoo and Facebook will shut down groups identified as pro-ana. However, others argue that censoring the sites will not prevent anyone from developing an eating disorder and that pro-ana sites may actually help friends and family members identify loved ones suffering from disorders. Livejournal and MySpace will not shut down pro-ana groups, but have worked with advocacy groups to place advertisements for recovery groups and treatment services on the sites (BBC News 2008).

Scholars and activists who call for more representative portrayals of women in media and fashion often cite the prevention of eating disorders as one of their aims. In 2013, Israel passed a law that bans models with a BMI under 18.5 from catwalks and commercials and requires advertisers to include a notice on images that have been photo-shopped. The legislation was partially inspired by the death of Israeli model Hila Elmaliah from anorexia in 2007. Critics of the law, like fashion publicist Kelly Cutrone, defend the use of extremely thin models on aesthetic grounds, claiming that clothes look better on thin people (Roff 2013). Even eating disorder specialists are skeptical about claims that eliminating very thin women from mass media will end, or even

meaningfully reduce, the incidence of eating disorders. There are similar debates about claims that the increasing incidence of eating disorders is due to Western cultural influence, particularly exposure to Western media.

Diet and Body Size

Beliefs about body size and attempts to shape the body through diet vary widely around the world. The preference for thinness and practice of weight-loss dieting appear to increase along with affluence and Western influence; however, anthropologists estimate that 80% of human societies on record have a preference for plumper women. Just as thinness and restrained eating are associated with wealth and virtue in most industrialized Western countries, fatness and a robust appetite are seen as beautiful and healthy and associated with a higher social status in others. In some societies, like the Tuareg and Azawagh of Niger, men are supposed to be thin but women cannot be "too fat" and families who can afford it engage in deliberate fattening rituals to prepare girls for marriage (Popenoe 2004). In some parts of Puerto Rico and Greece, a woman getting fatter after her marriage is seen as a positive sign of her husband's success in providing for the family (Massara 1997). Some subgroups within Western countries also hold a positive view of fatness; African-American women and Latinas in the USA are more likely than white women to associate fatness with strength and beauty.

Some people argue that body size preferences (or perhaps all beauty ideals) are inherently problematic because they create and reinforce unfair social hierarchies, promote unhealthy eating behaviors and body dissatisfaction, and are particularly burdensome for women. Susie Orbach's influential 1978 book *Fat is a Feminist* issue argues that dieting and compulsive eating are both caused by gender oppression and constitute another form of oppression for women. Others argue that investing in beauty ideals is a meaningful form of cultural work related in complex ways to a society's values and that striving for thinness or fatness contributes to identity formation, well-

being, and social cohesion. There is broad agreement that weight bias has a negative impact on the social, economic, psychological, and physical health of people who do not fit prevailing ideals and that weight bias affects women more than men and poorer women more than richer women.

In countries where thinness is preferred, fatness is often associated with lower class status and marginalized racial groups. Women are typically expected to adhere to a lower ideal weight and experience more harassment about their weight and diet than men. In the USA, fatter white women earn less than thinner white women with the same jobs and qualifications; there is no difference for women of color or men. Fat women in the USA are also more likely to be depressed and suicidal and less likely to find dating partners or marry (Oliver 2006). Doctors and psychologists have been shown to view fat patients as lazy, lacking in self-control, noncompliant, unintelligent, and dishonest, and they perceive women as fat at a lower BMI than men. Educators say fat students are untidy, more emotional, and less likely to succeed than thinner students and have lower expectations for them across a range of ability areas. These stereotypes may lead to a lower standard of care and poorer academic performance and educational achievement, and the effects are greater for women, people of color, and the poor (Friedman and Puhl 2012).

Labor

Women do a majority of home food preparation around the world and play a significant role in commercial agriculture, industrial food production, and restaurants. Growing, processing, and serving food can be a source of power and pleasure for women and is widely seen as a realm of women's expertise. However, bearing a disproportionate share of the burden of food labor can also be a form of gender oppression, and women who work in food industries are subject to greater wage exploitation and more physical and emotional abuse.

According to the FAO, women produce more than 50% of the food grown worldwide. In

developing countries, 79% of women who work are primarily engaged in agriculture. Women farmers often face more challenges than men in getting access to desirable land, improved seeds, fertilizers, and equipment on average. The FAO estimates that women's yields are on average 20–30% lower than men's (Committee on World Food Security 2011).

Women do 85–90% of household food preparation in developing countries. In some developed countries, the share of home cooking done by men has been increasing for at least the last few decades, but women still do more of it. According to a 2012 time use study in the USA, women spend approximately three times as much time as men on food preparation and cleanup. Approximately 50% of women spend at least some time cooking on an average day while fewer than 20% of men do (Bureau of Labor Statistics 2013). Women also do a majority of the shopping for food and bear primary responsibility for the additional labor involved in feeding children, even when they work outside of the home.

Women employed on farms, in factories, and at restaurants are typically paid less than men in those industries and are at greater risk of rape and sexual harassment in the workplace. A 2010 survey of women farmworkers in California found that 80% of respondents had experienced some form of sexual harassment at work. Twenty-four percent had experienced sexual coercion, which usually entails being offered quid pro quo like desirable jobs for sex (Waugh 2010). In meatpacking and food processing, women tend to be assigned to jobs that pay less, are less likely to be promoted, and are subject to more sexual harassment and assault.

Women restaurant workers are more likely to work in tipped positions, which have a lower guaranteed minimum wage, and are less likely to be promoted or assigned to managerial roles. Only 11–18% of chefs are women, and women chefs earn an average of \$14,851 less than their male counterparts (Villanueve and Curtis 2011). On average, women in the restaurant industry in the USA make about 79% for every dollar earned by men, which is comparable to the national gender wage gap.

Cultural Capital

In addition to all the material ways food reflects and reproduces class hierarchies, food is also implicated in the hidden or “soft” forms of domination that operate at the level of aesthetic tastes, habits, and social dispositions. The term “cultural capital” comes from *Distinction*, Pierre Bourdieu’s 1979 study of the preferences of different social classes in France. He argued that the upper class preserves its advantages in part by making “good taste” more difficult to acquire. In keeping with his theory, the kinds of culinary knowledge and eating practices constructed as aesthetically and morally superior (often characterized by words like elegant, polite, refined, or sophisticated) are generally those that only the wealthy can afford to cultivate. The foods and eating practices of the poor and working class tend to be characterized as coarse, rude, disgusting, or uncivilized. Tastes and habits form the basis for judgments about intelligence and moral character and sometimes determine access to exclusive spaces and opportunities.

The cultural capital associated with food may be particularly important to women because cooking, entertaining, and teaching children etiquette have all traditionally been feminized. In contemporary Western countries, most mass media in the “lifestyle programming” genre, which seeks to educate audiences about things like food and home decorating, is aimed at women. Media scholars Kathleen LeBesco and Dean Naccarato argue that the genre as a whole and star performers like Julia Child and Martha Stewart reinforce class by giving their largely female audience the illusion of mobility (LeBesco and Naccarato 2008).

Class-based and gendered attitudes towards food also shape social movements aimed at improving the food system. In the USA, the Pure Food and Home Economics movements of the late nineteenth and early twentieth centuries and the Slow Food and locavore movements of the late twentieth and early twenty-first centuries have been largely led by white, middle- and upper-class women. Particularly in the case of the Pure Food and Home Economics movements, women’s

participation has been attributed to the Cult of Domesticity and hailed as a kind of feminism. White, middle-class American women learned to work within and simultaneously expand the domestic sphere by pursuing political change through their accepted roles as mothers, caretakers, and managers of the home (including, crucially, the kitchen).

However, women’s empowerment through food activism may have come at the expense of other groups, particularly immigrants and the poor. Participants in these movements often espouse populist aims and sometimes claim to be specifically working on the behalf of immigrants or the poor, who are particularly vulnerable to the abuses of industrial food production – especially unsafe and unhealthy products and unsafe working conditions. However, by pathologizing the way immigrants and the poor eat, they also perpetuate prevailing cultural hierarchies. The Slow Food and locavore movements have been widely criticized for perceived elitism and advocating a narrow form of activism based on consumption that effectively excludes the poor and working class.

Summary

The primary ethical questions raised by the relationship between gender, class, and food concern the ways food can reflect and reinforce inequalities. Women and the poor in developing countries are more likely to experience chronic hunger; women and the poor in developed countries are more likely to be food insecure. Women are more likely than men to develop eating disorders, which may be more common in the middle and upper classes or simply underdiagnosed in the working class and poor. In some cultures, fatness is seen as beautiful and women are encouraged (or forced) to eat a lot in order to become fat; in others, thinness is preferred and women are encouraged to restrict their consumption. Women do the majority of the domestic labor of growing and cooking food worldwide and face wage discrimination and sexual harassment when working in food industries. Eating, dieting, cooking, and

working with food may be a source of pleasure and power for some women some of the time but can also be a source of oppression. Tastes and manners are used to distinguish people of different classes, and social movements led by middle- and upper-class women may perpetuate class hierarchies through the cultural politics of “good taste.”

Introduction

What is food? Central to any discussion of philosophy of food is a description of what the term “food” can mean. One way to conceptualize food is by reference to its intended use, to look at the ends to which food is put. This is an explicitly teleological approach, by which a thing, in this

case food, is made sensible by reference to the goal and outcome that a user has for the given thing. On the teleological account, an action becomes sensible by recognizing three things – the reasons that a person has for acting, their action, and the outcomes of that action (Henschke 2012, pp. 58–60). This entry makes sense of food by reference to the different outcomes that a person might have for food.

A specific case example of a specific food type, bread, is used through this entry. Six purposes for food are described: basic survival, quality of life, pleasure, personal relationships, cultural expression, and trade. Note that all six purposes understand food by reference to some form of consumption – that is, a commonality to all purposes of food is that it has been, is being, or will be consumed. Finally, while many of the purposes can be attributed to non-human consumption, this entry is focused on food as it relates specifically to humans.

Background

Bread is a common food for many people around the world. This might be as a packaged pre-sliced loaf purchased in a supermarket, as fresh-made accompaniment to a restaurant meal, or baked at home. The bread might be made from wheat flour or other grains, it might be leavened or unleavened, and freshly baked or days old. Bread will be used as an illustrative example for each food different purpose identified in this entry; however, many food types should and will fit to the different purposes.

Common to bread, and all other food types, is that people eat for reasons. Variability comes in with the reasons that a person might have for eating: the same piece of bread might be eaten to prevent starvation, to celebrate a particular cultural event, or to distract a person while working at their desk. The variability of purposes that a person might have for eating can mean that the bread, and food more generally, is valued differently. At a population level, these values can assist in determining what sorts of food get prioritized – The World Bank's *AgResults: Innovation in*

Research and Delivery program, for example, funds agricultural research based on expected impacts on that a food product will have food security, food safety, and on the promotion of health and nutrition (The World Bank 2012).

On an individual level, the values ascribed to a certain food type are said to operate as heuristics in assisting food choices (Connors et al. 2001). Keeping to the individual, consider the difference between eating a piece of bread to prevent starvation or as part of a cultural ritual. If the bread is keeping a person from starving to death, its value is (at least) in individual survival, while if the bread is part of an elaborate cultural ritual, its value is (at least) in the symbolism and maintenance of practices of the given culture. Depending then on how one considers the different values, the bread can have different levels of importance. On occasions these values can conflict. Should a limited supply of bread be used to save a person from starvation or should it be used for a well-fed cultural group to maintain their cultural traditions? Recognizing the different purposes for food promotes a better understanding of food itself and may help understand and resolve value conflicts about food types and resources.

The six purposes identified in this entry are commonly found in discussions of food, though they may be implicit in how people understand food. In *Managing Values in Personal Food Systems*, for example, five key values of food have been identified: health, taste, social relationships, cost, and time (Connors et al. 2001). For this entry, *health* is broken into “minimum survival” and quality of life, *taste* is located under “pleasure,” *social relationships* has been broken into personal relationships and cultural expression, and *cost* and *time* have been located under “trade.” As with much work in conceptual differentiation, the categories overlap, the boundaries between them are fuzzy, and others may carve up the terrain differently. The intention here is to capture and illuminate key purposes to which food is put.

Purpose 1: Minimum Needed for Survival

An immediate and obvious way to understand food is by reference to survival. That is, what is

the minimum amount of food needed to prevent death and/or maintain a person's life? The United Nation's Food and Agriculture Organization (FAO) uses a series of indices to identify and rank hunger around the world. Central to the FAO's indices is the "human energy requirement" element. These are "estimated from measures of energy expenditure plus the additional energy needs for growth, pregnancy and lactation" (Joint FAO/WHO/UNU Expert Consultation 2004). The basic premise to the human energy requirement is that if a person expends more energy than they consume, after a given period time, they die. At an individual level, the energy requirement "is the amount of food energy needed to balance energy expenditure in order to maintain body size, body composition and a level of necessary and desirable physical activity consistent with long-term good health" (Joint FAO/WHO/UNU Expert Consultation 2004).

This human energy requirement is a coarse measure, and as Edoardo Masset describes, there are a series of ways to see how such indices are calculated and how they relate to combating extreme hunger (Masset 2011). Further, Scott Wisor has argued that when using things like indices of hunger measurement to allocate resources, these indices have important ethical assumptions and ramifications (Wisor 2012).

In the instance of food for survival, bread illustrates the concept by being eaten to prevent starvation. For whatever a given day, a person would need to eat bread with energy that provides energy that, at very least, is equivalent to the person's energy output/use. If their consumption of bread (as their only energy input) persistently sits below the level of energy output, then the bread is not meeting its purpose of sustaining the person's life.

Purpose 2: Quality of Life

The human energy requirement is one aspect of food, and while maintaining a particular energy balance may prevent a person from starving, energy alone is not sufficient to maintain and assure a quality of life – food is also consumed to supply macro- and micronutrients. Given the important causal role played by malnutrition in public health (Müller and Krawinkel 2005),

understanding food by reference to hunger alleviation and minimum energy requirement alone captures only part of the importance of food for quality of life. Olaf Müller and Michael Krawinkel differentiate between protein-energy malnutrition and micronutrient deficiency (Müller and Krawinkel 2005), with protein-energy tying more closely to purpose 1, minimum food needed for survival.

Treating protein-energy deficiency "can benefit from preventive interventions ranging from income generation and nutritional education to maternal support, food supplementation and food prize subsidies" (Müller and Krawinkel 2005, p. 282). In contrast, "micronutrient deficiencies would best be addressed through food-based strategies such as dietary diversification through home gardens and small livestock" (Müller and Krawinkel 2005, p. 279). Energy input may be necessary for quality of life, but it is not sufficient – if food is considered in relation to quality of life, then the food consumed must also provide basic nutritional requirements.

To illustrate the importance of a distinction between basic energy input and nutrition, consider that there are now people who are obese but suffering from malnutrition (Kaidar-Person et al. 2008). Their basic calorific intake exceeds their energy output, they are not starving. In combination with other causal factors for obesity – see obesity-related entries in this encyclopedia – the quality of food that they are consuming is such that their nutritional needs are not being met. If one considers that food must meet basic nutritional requirements, then a diet that does not reach these requirements could arguably be said not to be a diet rich in food. Michael Pollan, for instance, states that "most of what we consume today is, strictly speaking, no longer food at all" (Pollan 2008, p. 7).

To counteract nutrient deficiencies, some modern food development and production use particular methods to increase the micronutrients found in common food types. One method is biofortification, in which micronutrient deficiencies in things like vitamin A, iron, and zinc are enriched through selective plant breeding (Nestel et al. 2006). See the Functional Foods entry in this

encyclopedia for more on this issue. Other methods include addition of micronutrients at the processing stage of commonly eaten products. For instance, low folate levels are associated with neural tube defects which are detrimental to fetal health. As such, many governments have instituted folate awareness campaigns, and some have actively sought to supplement processed breads and breakfast cereals with folate to increase fetal health (Buttriss 2005).

In the instance of food understood as quality of life, bread consumed for energy alone is not sufficient. The bread is eaten to provide nutrients above and beyond its energy provision. Some diets are high in energy but low in other nutrients – eating large amounts of bread alone is likely to reduce a person's basic health and may bring about a state of obesity. In order to prevent malnutrition, certain grains are designed through breeding or other technological interventions such that breads produced from them are high in micronutrients. Further, given the commonality of bread in many people's diets, adding nutritional supplements to bread can be a method to provide these missing nutrients to a large swathe of a given population. The addition of folate to bread, to prevent birth defects, is one such example.

Purpose 3: Pleasure

A further obvious reason for eating is pleasure. Food tastes good, and the feeling of satiation can also be a source of pleasure. The bases for such pleasures are broad and are likely to be somewhat idiosyncratic. Four ways to carve up the pleasures gained from eating are taste, satiation, neurological stimulation, and challenge.

The most obvious pleasure that comes from food is when it tastes good. For many people, in the developed world at least, concerns of survival and nutrition are secondary to the first question – does the food taste good? Certain food types and combinations likely trigger particular neurological stimulation, such that some foods will typically taste good to the average person. Taste, however, is more complex than simple stimulation/response; contextual factors play an important role in how food tastes. Brian Wansink details a series of different events and experiments where

the color of food changed how it tasted to people and how the region that a wine was said to come from changed not only the taste of the wine, but also of the accompanying meal (Wansink 2006, pp. 120–122, 119–123).

A second pleasure that comes from food is satiation or the feeling of fullness that comes from a particular meal. While satiation may be considered a quantitative aspect of food, where the pleasure of taste is a qualitative measure, contextual factors are also in play. For instance, according to Wansink, “scientists don't know what makes us full. It seems to be a combination, among other things, of how much we chew, how much we taste, how much we swallow, how much we think about the food, and how long we have been eating” (Wansink 2006, p. 46). Further, Pollan describes the unit bias, whereby people register a feeling of fullness in part by reference to completion of a unit of food (2008, p. 183). On the unit bias, the way the food is packaged and presented will impact how satiated people feel upon eating a given amount of the food, a point supported by experiments done by Wansink (2006, pp. 16–19, 42–47).

A third aspect of pleasure comes from the neurostimulation produced by certain food types and combinations. David Kessler describes the role of sugar, fat, and salt in triggering predictable release of the pleasure-causing chemicals, the endorphins (2009, pp. 36–38), and their role in keeping the brain thinking about pleasurable foods through the release of dopamine (2009, pp. 41–45). Kessler's argument is that sugar, fat, and salt can trigger these neurochemicals independently and that when they are combined in a specific food serving, the pleasure and reward produced by consumption is increased, prompting Kessler to argue that such oversaturation is a common causal element in overeating (2009, pp. 58–64).

The fourth aspect of pleasure comes from challenge. As Carolyn Korsmeyer puts it “[t]he remarkable thing is not just that we managed to eat, but that we managed and continue to take considerable *pleasure* in foods that present us with challenges to both our senses and sensibilities” (emphasis original, 2007, p. 145). She

describes the challenge of eating spicy foods or even food so close to rotten or still served alive to as an almost disgusting challenge from which people derive a deep pleasure (Korsmeyer 2007). Pleasure derived from food is thus a complex set of pursuits, including simple taste, satiation, neurostimulation, and even disgust.

Bread here becomes something more than a simple delivery of energy or nutrients – the flavor of a fresh home-baked sourdough is quite different to a stale slice of industrially processed bread. Load the bread up with additional ingredients tomato, chili, mozzarella, and olives, and it becomes a pizza, consumed for pleasure, and quite distinct from any thoughts of survival or health.

Purpose 4: Personal Relationships

Different to the reasons discussed so far, this fourth reason touches upon food's role as a symbol. In particular, food is used as a symbol of the relations that exist between different people. "Eating together is a primary marker of kinship and belonging" (Higman 2012, p. 149). Meals taken at home are a paradigm example of this. Within the home, the preparation and consumption of meals has indicated status. In recent times in the developed world, the role of producing and feeding the family fell primarily on the women (Higman 2012, p. 145). Further, the exclusion of people from consumption with the dominant group signified and reified class distinctions to identify caste or house servants (Higman 2012, pp. 149–150).

In conjunction with cultural expression, food choices can also play a central role in individuation and self-identification. Think of the self-chosen status of vegetarians. Above and beyond maintaining a diet free of meat, publicly self-identifying as a vegetarian does more than simply hold to a set of moral values – for some, the public stance of vegetarianism is essential to creation and maintenance of a particular moral character. "[T] here is no *you* prior to your choices and actions, because your identity is in a quite literal way *constituted* by your choices and actions" (Emphases Original, Korsgaard 2009, p. 19). Food can indicate the existing status of relations between people and can also be a central element of self-creation.

Bread now takes on a roll whereby it may be made by a servant, to be eaten fresh by the master, and later consumed stale by other servants. The variability of service shows the existing power relations between people, even within one household. It can also symbolize a set of moral choices – a family sits down to eat a meal of roast chicken and fresh bread. One family member, a vegetarian, limits their consumption to bread alone, indicating a certain set of moral characteristics, individuating themselves from the rest of the family.

Purpose 5: Community

Extending from the idea of food as relational and individuating, consider food's role in marking out cultural identities. Two immediate forms spring to mind – food's role in religious communities and food's role in geographic communities. Paul Thompson is worth quoting at length here: "Connecting food with community is actually a commonplace. A community event without food is rare, and the bonding people experience when sharing food and drink underwrites a number of diverse human institutions. The family table, dinner and a movie, the church supper, the wedding banquet, and the business lunch are icons of sociability, each centering on a meal but implying distinct forms of common interaction and shared meaning among human beings" (2010, p. 145).

Like the vegetarian, consider first cultural prohibitions around certain food types, here called food taboos. Food taboos are said to play a major role in the formation and maintenance of a community's identity. "Food taboos are not the only significant prohibitions raised up by ideology and identity-making, but they are probably the most persistent and widespread. . . This stems from the central role of food in defining and creating cultural and national identity, long after nutritional or medical justifications are abandoned or forgotten" (Higman 2012, p. 45). Adherents of Hindu, Islam, and Jewish religious faiths have particular prohibitions as central to their identity. Some of these taboos may consist in direct prohibitions, such as the sacredness of the cow in Hindu beliefs (Higman 2012, p. 46) or may involve particular necessary rituals, resulting in a food to be considered *halal* or *kosher* (Higman 2012, p. 45).

Of course, religious practices are complex and involve much more than prohibitions and rituals. Consider the eating of the communal bread as part of certain Christian rituals. Further, consider the role of certain feasts within religious practice (Thompson 2010, pp. 145–146). The consumption of certain foods at certain times can be central to a given cultural identity.

Food also comes in a range of geographically identifiable types. Walk through a “food district” in many cities and there will be a range of restaurants announcing their dishes by region: *Italian*, *Indian*, *Indonesian*, and *Iranian*. Definition of food by reference to a country does more than advertise the tastes offered by a particular restaurant. Such geographic identification can be shorthand for a patriotic diaspora, maintaining certain food practices away from the country of origin to help maintain a community. Like the vegetarian, such adherence to a geographic origin can express a willful identification with one’s past. As Thompson puts it: “[F]ood can be a focal thing. . . when it becomes the centering orientation that holds a number of meaning-giving activities together, providing coherence and purpose to our lives” (2010, p. 136). Food, the particular ingredients used, the rituals associated with its production and consumption, give meaning to communities and can be key ingredients in reifying the existing community identity.

Bread can be, for some, the symbol for their faith. For others bread can be a link to a homeland, left behind and sometimes, never visited. Consider the Italian sandwich, the Panini, compared with the Indian paratha. Both are bread and may use similar ingredients. But despite the obvious differences in taste, they both serve an additional purpose symbolizing a people’s cultural legacy, providing individuals with a link with a country of origin and permitting a living and healthy community, far away from this country of origin.

Purpose 6: Commerce and Trade

The final purpose for food sees its production and consumption in instrumental terms. That is, food is produced for consumption by others, such that those in the production chain function within a market economy. Barry Higman makes two

complementary claims about food and trade – firstly that the trade in food was and still is dependent upon preservation and transport technologies. Secondly, it was trade in food, in particular exotic spices, that was a key driver for the development of early trade networks (2012, pp. 125–142). On Higman’s account, the trade in food was central to much development of human history. Here, the concomitant development of technologies becomes central to understanding the trade in food and the social changes that occurred as a result – “Only with the development of efficient and reliable technologies of preservation did the long-distance movement of many commodities become viable, and only with the development of modern technologies of bulk transportation did it become profitable to move great quantities of basic foodstuffs around the world” (Higman 2012, p. 126).

On the food as trade model, the general numbers of producers can decline as farmers become more specialized, focusing on increasing outputs from the given land and inputs. “The ethical argument for such specialization is that when goods are produced at the least possible cost, they can be sold at the lowest price. This means that people who eat (all of us) spend less on food, freeing up more of their income for other things, and low-cost food is especially important for those who have the least income” (Thompson 2010, p. 31). Such specialized practices can be environmentally harmful (Roberts 2008, pp. 208–236). Further, as Thompson notes, such specialization can come at a price to the agricultural communities themselves (Thompson 2010, pp. 33–41).

The importance of understanding food as trade is that this purpose can not only override the other purposes, but in some occasions, can actively undermine the other purposes. For instance, a snack food company may design a food product to be highly palatable, containing an ideal mixture of sugars, fats, and salts (Kessler 2009, pp. 12–17). The particular combination in this snack food increases the likelihood that consumers will eat this snack food, that is, will increase its trade. However, heavy consumption of this snack food might promote obesity and reduce basic nutrition. The snack food may also

compete with existing cultural practices, such that the consumers lose connections to their traditional food types, and/or local food cultures may be outcompeted by the highly desirable snack food. Yet, presuming that obesity and/or the decline of local cultures are undesirable, seeing food only as trade overlooks these negative impacts.

Bread here fits the idea of food as trade in two ways. Firstly, that bread is produced for the purpose of selling. In this way, the bread is just a tradable item, equivalent to any other widget. Secondly, the practices in and around its production are mere instrumental practices designed to maximize tradable output: a plot of land is farmed to produce wheat for flour and is deemed productive when its output meets some desired level of profitability. Again, the growing of the wheat is secondary to profitability; the bread that is produced is valuable insofar as it makes a minimum level of return on investment.

Summary

This entry looks at the idea of making sense of “food” by reference to the purposes that people might have for that food. This entry follows the same generic food item, “bread,” to show that while “bread” may remain bread, its meaning and value changes as the purposes for its consumption change. People may eat bread to survive, to have a minimum standard of living, to have pleasure, to develop and maintain personal relationships, as an indicator of some cultural importance, or as a tradable good. Implicit in this entry is that these different purposes can and do conflict. The recognition of the different purposes of food can help to identify and resolve some of these value conflicts.

Food-Body Relationship

Synonyms

[Diet](#); [Embodiment](#); [Nutrition](#)

Introduction

Food circulates materially (in the digestive system, supermarkets, dinner tables, school, hospital, prison cafeterias, etc.) and symbolically (in TV shows, religious rituals, feasts, etc.) to produce our bodies as socially, politically, and physically constituted transitional entities. Eating habits are key to the interrelated constitution and practice of ethnic, racial, gender, and political identities. Food is equally important in the production of the cultural and social codes and norms that affect our bodies and our experience of self as physical beings. Food consumption involves time- and place-specific arrangements, and the body as corporeal space is sexed, built, and (re)designed through every day and lifelong practices of food and eating. Our bodies are a product of simultaneously social and physical interactions with food which transform according to changes in the life course, exchange relations, and environmental and other factors. For example, the relationship between food and body relates to life course transitions since diet-related factors influence children's bodies differently than teenagers', adults', and older people's. More specifically, younger

bodies are more exposed to disciplinary patterns of eating imposed by parents, state institutions (e.g., school programs, medical specialists), and the broader social conventions of the cultural (e.g., religious dietary observance within the society, commercials) and ecological environments in which they live. Thus, the habitual food environment to which a child is exposed is often the emotional and sensory basis of her personal food choices later in life. Eating disorders (over- or insufficient eating) which affect younger and older adults also have crucial ties to one's relation to food and bodily experience in the formative years of developing food habits during childhood.

Through food, individual bodies connect to multiple intersectional abstract categories including the self, masculinity/femininity, and broader structures such as the nation (Lien and Nerlich 2004). This entry touches upon these linkages and covers the relationship between food and the body under five subheadings followed by a conclusion: the first subsection overviews four transformative moments within the Western history which mark important shifts in ethical problematization of food and bodies. The focus is on Plato's writings in *the Laws* (1967–1968), medieval Christian monastic practices, post-medieval social transformations, and the modern scientific turn in nutrition science. The second subsection introduces the concept of embodiment in order to address the so-called body-mind division within much of Western thought and to present the significance of mental/emotional perceptions and practices of self and body in interactions with food. The third subsection introduces gender as an organizing social category in configuring the food-body relationship. In the fourth subsection, the emphasis shifts to a broader range of social categories which operate and mark certain bodies as “distinct” along ethnic, cultural, medical, and class-based links to food regimen. The final subsection focuses on ritualistic and activist forms of self-starvation in order to exemplify the diversity of motives and patterns behind fasting as an exceptional bodily way of relating to ethical (non)eating. The conclusion recaps the arguments and themes introduced in the entry.

Bodies and Food Ethics in Western History

Several key shifts in Western history and thought inform our knowledge of the development of ethical concerns with food and eating habits. Based on three different contexts, the shifting notions of food ethics will be depicted by focusing on the problematization of its elements: means, objectives, and scale.

In ancient Greece, food ethics, or “dietetics” as Michel Foucault refers to it in *The Use of Pleasure* (1985), involves individuals as active observers of food intake and individual diet. In *Laws*, Plato (1967–1968) explicitly addresses diet as a constitutive regime “which [is] either good or bad for their bodies, and equally able to affect similar results in their souls” (5747e). For Plato, ethics is the level of relating to oneself through certain techniques and priorities in order to achieve self-transformation. Ethical transformation of the self is both a contemplative and practical domain of strategic design to achieve virtue. For him, this knowledge is particularly important because it is transferable to politics. The body and its need to be nurtured is an important aspect of the ethical transformation of the self. The notion of the (ethical) self as something to be cultivated and maintained across all spheres of life including the everyday makes food important to Plato’s idea of moderation to constitute the virtuous life through self-transformation. Since food is capable of nurturing and damaging both the souls and bodies of men (Foucault 1985), when it comes to feeding the body, moderation in the amount and type of foodstuffs is a virtue. Yet, what moderation entails and how it should be practiced are subject to individual interpretation. Put differently, moderation is a technique in which eating habits should be designed (reasoned) to constitute the ethical subject, and body is both the domain and the product of this effort to constitute the ethical self. As such, we can say that the Platonic notion of a proper diet is more focused on the process, that is, moderation, than the body that is its end result. Moderation involves reasoning as its method. Reasoning is used to judge what is available, edible, and good in nature in order to

achieve and maintain a moderate diet and benefit from its advantages on the mind. For Plato, one is capable of fashioning eating habits in a virtuous way through reasoning, and the body is both the scale and the means to realize such ethical standards.

The ancient Greek notions of private/individual food and eating decisions radically differed from the institutional engagement of the medieval church in imposing a collective food morality on the masses. The medieval Christian obsession with defying the flesh and abstaining from its desires led to a major shift in everyday and ritualistic consumption of food. Monasticism – metaphorically and actually – affected associations of food as an instrument of self-discipline. In the ancient Greek constructions of the food-body relationship, food was a resource for survival and a means for self-transformation in order to participate in the production of virtuous (public) life. Medieval Christianity, in contrast, reinterpreted virtue through self-sacrifice and mortification. Self-transformation was only possible through the disregard of the mortal body and its needs and pleasures in order to free the soul from the burdens of the flesh. As such, unlike the ancient Greek notion of the body as a means of cultivating the ethical self, Christian morality of the Middle Ages targeted bodily pleasures as a barrier to spiritual progress. The ecclesiastical emphasis on mortification and refrain from bodily desires reordered much of privately exercised routines of individual and social life. Like sexuality, food intake was among these previously private spheres of life. As such, Christian understandings of care for the self (soul) redefined the food regimen and manners of individuals and masses. The disciplining of individual bodies at the same time introduced new and collective food consumption patterns such as cycles of fasting and festivals.

In *The History of Manners*, German sociologist Norbert Elias (2000) explores how postmedieval European values regarding violence, sexual and bodily behaviors, table manners, and interpersonal communication gradually transformed into what we today broadly call etiquette or socially acceptable behavior in most Western societies. Elias relates these developments to increased

feelings of shame and disgust, which increasingly standardized “self-restraint” as a norm within education and all other fields of societal interaction. According to Elias, it was during this “civilizing” movement that the importance of food in public life was back on the agenda. This was mainly because moderation and refinement were once again considered the means and objective for a virtuous life primarily among the societal elites but gradually through the masses. Along with other bodily functions, eating was problematized in order to civilize individual bodies through self-control and self-restraint in public exposure and social interactions. As such, development and refinement of table manners and changes in food preparation during postmedieval transformation incorporated food and eating practices as markers of social status and differentiation.

The modern scientific turn introduced the impacts of food intake and its influences on body weight, health, and social implications of bodily existence. As populations replaced masses as the targets of political authority (Foucault 1991), scientific approaches to agriculture and nutrition became increasingly more important in establishing political order and stability. Political and scientific concern with food availability and sufficiency in relation to population management influenced reconceptualization of food ethics at a collective rather than an individual level. Contemporary challenges, mainly about environmental degradation of agro-food resources and the inequalities in access to nutritious, culturally appropriate and affordable food, reflect the grounds on which individual and social dimensions of moral concern with food are reestablished and mutually inform each other.

Historical transformations in how food habits function in our conception of body and self are important in making sense of the current configurations of food-body relationship at the individual and social levels. In terms of the differentiation of its means, food ethics has moved away from reasoning and moderation towards monastic discipline and later towards discipline in the form of modern self-restraint. In terms of the objectives, for Plato, ethical problematization of food is a means to help cultivate the virtuous self through

physical maintenance and training of the body together with the mind. On the other hand, the medieval obsession with bodily abstention and moralizing food and eating habits aimed at salvation by denying the flesh. Still disciplinary in nature, the objective of the postmedieval notion of food ethics was higher and universalized standards of civility and social behavior. Finally, in terms of the scale for conceptualizing and applying a food ethics, Plato’s emphasis was on the individual who was supposed to apply reasoning and differentiate between the good and bad food for himself. On the contrary, both the medieval emphasis against pleasurable eating and the civility movement problematized food ethics for the masses, and they were both organized on a collective basis – through religious, educational, and other institutions such as the family.

Food and Embodiment

Body and mind are considered dichotomous categories within much of classical Western philosophy. Embodiment is one way of challenging this dichotomy and conceptualizing ourselves as physical, bodily beings who exist, interact with, and make sense of other corporeal, ecological elements through sensory, mental, and emotional means.

Within the history of Western thought, it is conventionally the body that is subordinate to the mind. The body is mostly theorized as an instrument which is either defied or well kept for the proper functioning of the mind: its mental faculties and spiritual qualities. The Western neglect of the body as secondary to the mind also relates to the patriarchal associations of mental processes such as creativity, analytical reasoning, and philosophizing with superior notions of masculinity. Within the patriarchal traditions of Western thought, the body is associated with femininity because of its transitional, vulnerable nature, and dependence on mundane necessities such as the need to be fed. Unlike the analytical functioning and universal qualities of the rational mind, the physical dimension is superficial because bodies are prone to desire, are destined

to change, and are therefore instable and unpredictable. Due to the subordinate role of body within this deep-rooted dichotomy, food per se has generally lacked an emphasis as a crucial domain of our perception and practice of selves.

Subjective dimensions in eating (sensory, emotional, memory) play a key role in defining the food-body relationship as a continuum of embodied practices and awareness. Bodies are exposed to various material and social elements, including food, in processes of socialization. The material and social conditions of access to and consumption of food constitute the embodied self. The totality of these processes translates into sensations of taste, pleasure, comfort, and/or discomfort at the individual level. Since eating is an embodied action, most interactions with food and eating are also mental processes and are linked to – often multiple – emotions. The most emphasized emotions tied to eating are guilt, comfort, and success, which are mostly explored in terms of excessive or under-eating habits. Yet, not only in relation to eating disorders, the sensory experience of anyone while eating or in a food environment is a cumulative product of pleasurable or discomforting memories of past experiences. The embodiment perspective suggests that the negative and positive attributes resulting from the physical performance of eating inform our experience and awareness of our selves, ideas on others, and how we make sense of the world in general.

Food is central to the corporeality of social life both for human and nonhuman animals (Shilling 2003; Turner 1996). Embodiment problematizes the role of the physical body in constructing the social categories resulting from corporeal actions. Nutritional, health-related, and/or mystical qualities of foodstuffs and eating habits are influential in characterizing power, beauty, and well-being as embodied processes carried out and maintained through food choice. From individual families to national/regional cuisines, food-related actions and meanings reproduce shared experiences and promote social and material interactions within a group. Although social associations of food are relational and vary over time and across cultures,

food choice and diet are the primary markers of the uneven geographies of the corporeal scale. Bodies are politicized, criminalized, pathologized, and sexualized through practices such as dieting, fasting, and starvation. As embodied actions, bodily experiences of food are social processes in which the nutrients interact with conceptions of the self and the construction of intersectional identities. As such, embodiment addresses the equally physical and mental actualities of food such as cravings, hunger, and pleasure based on an integral understanding of the body-mind relationship (Hayes-Conroy and Hayes-Conroy 2008).

Food and Gendered Bodies

For most cultural and historical constructions of the food-body relationship, notions of food-related care and nurturing are associated with femininity and women. Nurturing and femininity are mutually constructed categories that operate through embodied actions. Gendered subjects – both male and female – attribute meanings to and are defined by the everyday experiences of producing, processing, and presenting food since food is typically prepared by female (care) workers at home and outside the domestic realm. Reproductive actions such as meal planning, shopping, and cooking are strongly associated with femininity and the caregiver status of women within the patriarchal family structure.

Food is prepared in kitchens and shared in homes, both of which are intensely associated with gendered notions of feminine domesticity. In this sense, food is one of the many symbols and materials that lead to the patriarchal arrangement of gender and women's status and roles within the family and the society. Gendered experiences of eating, preparing, and sharing food are related to processes where individual bodies link to places and temporal cycles at diverse regional, national, and international scales. To illustrate, as unpaid and paid household providers; teachers; child-care, elderly-care, and patient-care workers; and mothers, women are responsible for dietary planning, food purchasing, and cooking of

produce brought about by various agricultural policies, trade agreements, and cultivation methods. As care professionals, women all around the world work in fields and community gardens and regularly visit supermarkets, mega-markets, street markets, and local-organic farmers markets to negotiate the most affordable and quality food-stuffs they could provide for their dependants.

In addition to the everyday practicalities of food preparation and eating, preoccupations with body image also demonstrate the interrelations between food intake and gender. As both social process and embodied action, food interactions define the embodied constructions of feminine and masculine subjectivities. Feminine roles and experiences around the “lean body” discourse are connected to sexuality and the relationship between gendered partners. Despite the historical and cross-cultural variations in what constitutes the healthy body, food and eating habits play a crucial role in terms of the way bodies are sexualized.

Gender affects the symbolic realm and codes certain foodstuffs, body figures, practices, and spaces as masculine/feminine. Reference to the “gendered dimensions” of the food-body relationship is often understood as women’s dissatisfaction with their body weight, image, etc. Yet, empirical studies have shown that restrictive eating practices and concerns for a slimmer body image affect females and males differently in reconfiguring eating habits. For example, vegetarianism is feminized while red meat is associated with aggression, strength, and masculine power. Also, weight loss through insufficient food intake and self-starvation is more common among adolescent females than males who instead opt for high-protein alternatives to replace existing food preferences in order to lose weight (Nowak 1998). Despite the rich multidisciplinary literature on feminization of distorted body image perception (i.e., anorexia nervosa), restrictive/excessive eating, and the preoccupation with a fat-free body image, gendered implications of food intake in the construction and experience of male bodies and masculinity at various stages of life remain a relatively less explored dimension of the food-body relationship.

Food and Distinct Bodies

Eating preferences are identifiers of multiple broader categories relating to superior-inferior, healthy-unhealthy, and responsible-indulgent lifestyles. In other words, perceptions of social distinction, acceptability, and cultural appropriateness significantly mark food practices. Food practices have historically been an important line of demarcation between the privileged and underprivileged across the geographies of center-periphery, rural-urban, and diverse bodies. Intensely since the mid-twentieth century, the processes of agro- and gastro-capitalism and the popular and medical discourses of food choice have promoted the global circulation of food values, types, and tastes. According to the Russian critic and theorist Mikhail Bakhtin (1984, p. 281), “by taking food into the body, we take in the world” which includes all the power-imbued meanings, value associations, hierarchies, and practicalities that define our material lives and sense of self. These in turn greatly influence social patterns and experiences of distinction in relation to food and eating habits. Food consumption is an important domain of social and material interaction where social hierarchies and collective norms are produced, reproduced, and contested on an everyday basis and in contexts as diverse as festivity, drought, war, and other forms of political, social, and/or environmental crisis.

As an essential material commodity and a vital metabolic ingredient, food is consumed both literally and socially through embodied actions because of its associations with various forms of social power and status. Eating is a major identifier in the making of active/passive, obese, poor, ethnic, racial, working class, starving, ethical, ecological, and “beautiful” bodies. Individual food environments are also a means to establish the domain of “I” in relation to “others” in contexts of vegetarian, halal, organic, foodie, low fat, kosher, and foodscapes. For example, all of these influences, in turn, inform the ways individuals construct themselves as ethical, sinful, healthy, refined, and gendered subjects.

Ethical (Non)eating and Self-Starving Bodies

Embodied practices of food production, preparation, and eating are imbued by power and the inequalities surrounding broader social categories. Self-starvation refers to imposing self-inflicted limitations on food intake, effectively starving the body of the calories necessary to function properly. While this may be temporary and recurring, prolonged periods of starvation lead to severe organ damage and, eventually, death. Fasting, hunger strikes, and anorexia are different manifestations of self-starvation. They are also embodied expressions of self which target the body's dependency on food to survive. Nonself-inflicted starvation is often a corporeal manifestation of the broader social-environmental disparities, primarily, of poverty, famine, and war. Self-starvation, on the other hand, is intentional. It represents an embodied expression of the political and/or ethical disciplining of the body through its need to be nourished. The act also represents a different embodiment since the priority of the body in survival is superseded through an abstract, intuitive relationship with an external cause, ritual, etc. It is an intervention by the self to reorganize the priorities in the embodied experience of being alive. Self-starvation, thus, unfolds a process in which the body-mind integrity is reconfigured and the bodily need to nurture is contested on the way towards a morally defined self.

Fasting is voluntary refraining from eating for religious and ritualistic observances. Various configurations of the food-body relationship are at work in fasting practices. It is an embodied ritual whereby the self-starving subject denies the body its most basic need. The motives behind fasting differ historically and across cultures, religions, and rituals. Fasting may involve rewarding the soul and punishing the body, as well as regenerating and purifying both the body and soul. The ethical subject is active in disciplining the corporeal scale through food intake during fasting. Physical sensations arising from the imbalance between the body's need and the restricted food intake during periods of fasting are an embodied constitution of the subject as an ethical agent.

A hunger strike may be an individual or group act and refers to the voluntary refrain from food and/or fluids. The act may last for a predetermined period of time or as long as individual bodies resist the symptoms of starvation. The hunger strike is an embodied form of political resistance and may also be a means to support another form of struggle for a similar, often related, complementary political cause. Slow starvation during the hunger strike – the centrality of food in bordering life and mortality of the fasting body – reflects the vitality of struggle for the resisting self. The process also evokes a different relation between the bodily and private scales of eating and social understandings of political resistance.

Restrictive eating is another manifestation of self-starvation. Insufficient eating habits are intensely linked to control over one's body and increasingly shaped by the beliefs, statements, and practices surrounding the "healthy body." Dominant weight management discourses – particularly weight loss and fat management discourses – articulate body image as a massive public and individual health problem. A geographically informed approach to the lean and healthy body image debate presents waistline and BMI as indicators of the regional and gendered geographies of the self-starving body. Still, a link between weight management through restrictive eating and improving health is disputed.

Summary

This entry has examined the food-body relationship as anchored in the corporeality of food and eating habits. It has revisited instances and social categories where food is functional in the making of ethical, relational, gendered, sexed, and politicized bodies. It has emphasized that throughout history and across cultures of thought, food and eating practices have been an integral part of the moral concern around body and ethical constitution of self. Yet, it has also argued that these processes do not function in a single direction since subjective factors such as individual sense and emotions are also at work in negotiating,

accepting, creating, and subscribing to the ethical considerations developing around food and eating habits.

Introduction

Michel Foucault's writings from the *History of Madness* to the first volume of *The History of Sexuality* focus on the historical era between the late 17th and early 20th centuries and drew predominantly on French archives to analyze power relations in modern institutional settings. His best-

known works, dating from his "genealogical period," remain within this time frame and can be characterized as political rather than ethical in nature. In the last two volumes of *The History of Sexuality*, published shortly before their author's death, Foucault undertook what he called "modifications" in his research plan (Foucault 1990, p. 3). Rather than focusing on modern Western Europe, Foucault's final books examine ancient Greek and Roman philosophical sources in order to develop a theory of ethics as aesthetics of existence. Rejecting a view of morality as a set of universal rules, Foucault suggested that the ancient Greco-Roman models of ethics as self-care offered an alternative to Judeo-Christian and Kantian styles of universalizing and nomological morality. Technologies of self-care are enabling ways of transforming ourselves and can be understood as aesthetic practices of freedom and as a means of undoing the work of normalization. Ethics, for Foucault, was about self-transformation, becoming other than what one was. In particular, ethical practices could be undertaken to reverse and replace the effects of discipline that Foucault had examined in his earlier works.

Although never his focus, Foucault occasionally mentions diet during his genealogical period as an example of how power is written on the body and of how bodies are normalized. The example of "dietetics" is also examined as an extended example of self-care in Foucault's discussion of ancient Greek ethics. These suggestive passages, along with the diverse and productive ways that Foucault's work has been taken up by scholars working in the field of Food Studies, provide valuable insights for thinking about the ethics and politics of eating. This entry provides an overview of what Foucault wrote on food and diet as well as the manners in which these writings have been taken up by contemporary Food Studies scholars.

Foucault on Food

The following two sections will provide an account of Foucault's occasional and fragmentary

Interviewer: You do not fit the image of the sophisticated Frenchman who makes an art out of living well. Also, you are the only French person I know who has told me that he prefers American food. Michel Foucault: Yes. Sure. [Laughter] A good club sandwich with a coke. That's my pleasure. It's true. With ice cream. That's true. "The Minimalist Self": 12.

analyses of food and diet in his genealogical and ethical periods, respectively.

The Disciplining of Diet

In his 1971 article, "Nietzsche, Genealogy, History," Foucault describes genealogy as "an analysis of descent," and argues that "descent attaches itself to the body. It inscribes itself in the nervous system, in temperament, in the digestive apparatus; it appears in faulty respiration, in improper diets, in the debilitated and prostrate bodies of those whose ancestors committed errors" (pp. 82–83). Against the view that the body follows laws of instinct and physiology, Foucault insists in this entry that "The body is molded by a great many distinct regimes; it is broken down by the rhythms of work, rest, and holiday; it is poisoned by food or values, through eating habits or moral laws; it constructs resistances" (p. 87). "Effective history," he writes, "...shortens its vision to those things nearest to it – the body, the nervous system, nutrition, digestion..." (p. 89). Food, these citations suggest, is something that genealogy should attend to.

Although diet would never be a sustained theme in Foucault's own genealogies, there are indications of the normalization of alimentary choices in Foucault's lecture series at the Collège de France from 1973 to 1975 and 1974 to 1975, *Psychiatric Power* (2006) and *Abnormal* (2003). In *Abnormal*, Foucault argues that the monster was the genealogical predecessor of the abnormal individual targeted by modern psychiatry. According to Foucault, the paradigmatic monster during the Middle Ages was a fusion of man and beast. During the Renaissance it was the fusion of two humans in one body (the conjoined twin), followed by the fusion of man and woman (the hermaphrodite). By the time of the French Revolution, however, Foucault argues that monstrosity transitioned from being about hybrid morphologies to violations of laws of consumption. The monster became a creature of aberrant appetites. This appetitive monster took two major forms: the sexual monster and the alimentary monster. These two forms of monstrous appetite were sometimes

separated by class, with sex being the privileged vehicle for affluent monstrosity and food being the means of monstrosity for the starving classes. Thus, the sexual monster was captured by the figure of the incestuous aristocrat, while the alimentary monster was imagined as a cannibalistic peasant. Often the two forms of monstrosity fused in the social imaginary, as in the propaganda about Marie Antoinette, accused both of committing incest with her son and of having drunk blood from the skulls of Frenchmen. Foucault writes, "what constituted the point of formation of legal medicine, was... the existence of these monsters recognized as monsters precisely because they were both incestuous and cannibalistic, or because they transgressed the two great alimentary and sexual prohibitions" (pp. 101–102).

Despite this intriguing discussion of the alimentary monster, when Foucault traces his genealogy from monstrosity to abnormalcy, he considers only the sexually abnormal individual; the alimentarily abnormal individual remains unthematized. The reader is left with the questions: what became of the alimentary monster? Did the cannibal give birth to no "little abnormals" in the way that the sexual monster did? Can one trace a history of pathologized alimentary consumption, the way that Foucault traces a history of pathologized sexualities? In fact, reading Foucault's lectures from the previous year, *Psychiatric Power*, Foucault describes a case of a nineteenth-century individual singled out for psychiatric treatment based on his rejection of alimentary norms. The case involves a 30-year-old melancholic who spent his nights reading and refused to consume animal foods. Harangued by his housekeeper on the subject of his unwholesome lifestyle, he became paranoid that she would poison him (pp. 34–35). Part of his psychiatric cure was the prescription of a regime that precluded further relapses into folly. Since a rejection of animal foods is singled out as one of the symptoms of this man's mental illness, it is almost certain that the psychiatrically imposed regime entailed a return to eating meat, dairy, and eggs. However fragmentary, this case suggests that abnormal alimentary appetites, like abnormal sexual appetites, have been pathologized by

psychiatry from its birth or that diet, like sex, is a target of disciplinary power.

Diet as Care of the Self

Relations with others, Foucault claims, are the domain of power, which he had explored throughout his genealogical period, whereas ethics is the domain of how subjects relate to themselves or how they transform themselves. To approach one's own life ethically is, for Foucault, to see one's existence as an aesthetic project. This notion of the self as a work of art, or as something that the subject makes, was, for Foucault, refreshingly opposed to the modern, social science or psychoanalytic notion of the self as something inherent, to be discovered or deciphered. In writings from his final or ethical period, Foucault includes diet among the techniques of the self through which one may cultivate an ethical relation to oneself. Thus, although diet may be a target of disciplinary power, or may be imposed on subjects from without according to unchosen norms, it may also be a way that subjects cultivate their lives aesthetically, transforming themselves in self-chosen ways.

In an interview from this period, Foucault contrasts the ancient Greek preoccupation with controlling diet to the modern obsession with sex. "[S]ex is boring," Foucault says and notes that the contrary view is a relatively recent one:

[The Greeks] were not much interested in sex. [Sex] was not a great issue. Compare, for instance, what they say about the place of food and diet. I think it is very, very interesting to see the move, the very slow move, from the privileging of food which was overwhelming in Greece, to interest in sex. Food was still much more important during the early Christian days than sex. For instance, in the rules for monks, the problem was food, food, food. Then you can see a very slow shift during the Middle Ages when they were in a kind of equilibrium. . . . and after the seventeenth century it was sex. (1983, p. 229)

Foucault makes a similar point in *The Use of Pleasure*, when he notes of the ancient Greek texts that he is analyzing: "there is a limited space given to the problem of sexual relations compared with that according to exercises, and especially to food." (p. 114).

Although sex was of less interest than food for the ancient Greeks, eating and sex were considered similar kinds of activities and were approached in closely related ways. As Foucault writes, "This association between the ethics of sex and the ethics of the table was a constant factor in ancient culture. One could find countless examples of it" (p. 50). To take but the two most prominent examples, Plato would liken eating and sex in so far as nature makes both acts intensely pleasurable – and thus liable to abuse – in order to ensure that animals engage in them (Foucault 1990, p. 49). Aristotle would argue that one could only be accused of abuse with respect to eating and sex as these are pleasures involving the sense of touch; in contrast, one would not be considered guilty of self-indulgence for delighting in aural or optic pleasures or for passing up sex and a meal to appreciate a sunset or a musical performance (p. 40). Sex and eating are thus alike in that they are corporeal pleasures that risk being overindulged, and this made them critical ethical matters for the ancients, since their ethical thought was largely preoccupied with the virtues of moderation and self-mastery. The intense pleasures of food and sex threatened these virtues, thus posing considerable dangers to the good life.

In the "Dietetics" section of *The Use of Pleasure*, Foucault analyzes a number of ancient Greek "regimens" that provided guidelines for navigating the dangers of food and sex. Foucault notes that a regimen was a "manual for reacting to situations in which one might find oneself, a treatise for adjusting one's behavior to fit the circumstances" (p. 106). Once again, food and sex are treated in identical manners in these regimens, along with exercise, baths, emetics, vomiting, and other bodily evacuations. Foucault notes that such regimens are not universal codes about how everyone should act. They remain contextual; while the regimens suggest increasing or decreasing the frequency of sex in certain seasons, or eating boiled versus roasted foods, they do not forbid or prescribe any particular foods or food combinations or any particular sex acts or sexual partners. They do not say that any kind of sexual relation or cuisine is abnormal, unnatural, immoral, or forbidden, and they do not specify

what a “decreased” or “increased” amount of sex or eating means, as this would depend on the individual (his or her age, sex, health, and other activities). In these ways, the “dietetics” of the ancient Greeks were very different from the Christian codes of sexual morality that would follow, or, to take an alimentary example, from Kosher laws. What this suggests to Foucault is that subjects might approach sex – and by extension, food, drink, and other aspects of corporeal life – in a manner that allows them to manifest autonomy and to cultivate self-mastery rather than submission to disciplinary power. Moreover, these texts demonstrate that subjects might experience their sexual and alimentary lives in ways that are not structured by universalizing codes, prohibitions, prescriptions, or notions of normalcy.

When Foucault interprets these “dietetics” texts, and although he notes the relatively little space given to sex as opposed to food in them, it is the statements about sex that interest him. Thus, despite the space given to dietary regimes in his penultimate book, it seems that Foucault was interested in this example primarily because it was the context in which sex was written about in this era and because it demonstrated the contingency of our own interest in sex. As he writes, the example of the Greeks makes us ask of the contemporary era: “Why this ethical concern – which, at certain times, in certain societies and groups, appears more important than the moral attention that is focused on other, likewise essential areas of individual or collective life, such as alimentary behaviours or the fulfillment of civic duties?” (p. 10). It is thus significant to Foucault that food was once the focus of a complex set of restrictions and inspired a greater discursive interest than did sexual activity since he thinks that this is in marked contrast to the modern West, in which sex rather than food became the privileged site of moral restriction, scientific inquiry, and individuating reflexivity. Readers are left with the question of whether Foucault is correct in this assertion or whether diet has not returned as a significant site of both the disciplining of individuals and ethical self-transformation. As shall be seen in the following sections, contemporary food scholars have cast these assumptions of Foucault’s into doubt.

Foucauldian Food Studies

In the last dozen years, a burgeoning body of scholarship has emerged that draws on Foucault’s works in order to critically examine nutritional and psychiatric scientific claims about diet and to develop Foucauldian approaches to dietary practices and food ethics. In the following two sections, a non-exhaustive overview of writings in these areas will be provided.

Power/Knowledge: The Nutritional and Psychiatric Sciences

In *Food, Morals and Meaning: The pleasure and anxiety of eating* (2000/2006), John Coveney provides a Foucauldian genealogy of nutritional science. Much as Foucault provided accounts of the emergence of human and medical sciences such as criminology, psychiatry, and psychoanalysis, so Coveney approaches nutritional science from a critical historical perspective. The sciences that Foucault examined began within but then expanded outside of disciplinary institutions of confinement; likewise, Coveney explains that studies of dietary requirements began within nineteenth-century workhouses and prisons, then emerged in anti-medical health movements such as the Whole Foods movement, and were finally incorporated into medical science and practice through the discoveries of calories and vitamins. Knowledge of nutritional requirements was important within disciplinary institutions in order to determine the minimum amount and quality of food that could be fed to inmates while still maintaining the institution as a deterrent; the food had to be worse in quality and quantity than what the majority of the poor ate outside of these institutions. Later, when it was concluded that inmates in workhouses were for the most part “deserving poor” and children, food quality and quantity were regulated less as a deterrent than to serve a rehabilitative function (p. 66).

Coveney demonstrates that the study and regulation of nutrition not only emerged within disciplinary institutions but are deeply embedded in biopolitics, which, as Foucault defines it, is the management of populations by the state and state institutions (Foucault 1978). To give but two

examples of biopolitical investments in diet, nutrition became a political concern when state organizations considered how the poor could be made to eat in more cost-effective ways (p. 61) and when widespread malnutrition was associated with a dearth of recruits who met the physical stature requirements to serve in the Boer War (p. 78). While in several works (Foucault 1978, 2003, 2006), Foucault examines the manners in which disciplinary institutions interacted both antagonistically and collaboratively with the institution of the family, Coveney shows that biopolitical concerns for the health, able-bodiedness, and longevity of the population justified biopolitical and disciplinary incursions into the family in order to promote nutritional diets. Finally, just as Foucault shows that scientific or pseudoscientific knowledge has often been deployed for the purposes of moral or social hygiene, so Coveney examines the ways that nutritional science was, from the start, deeply entangled with morality: excessive, wasteful, unhealthy, sweet, rich, and fattening foods were considered “bad” (especially when fed to children) and “good” eating was associated with a thrifty, restrained, and wholesome diet. While Coveney considers the moral dimensions of eating in terms of such notions as waste, excess, and health, he neglects to consider the ways that nutritional science has been used to promote and to resist other ethical dimensions of eating; most notably, Coveney fails to consider moral concerns about nonhuman animals and the environment that arise when the biopolitical (nutritional, economic) advantages of eating their flesh and secretions are under consideration. He does not explore the ways that scientific claims about nutrition have been deployed both by those who advocate for the eating of animals and by those who resist this diet.

In contrast to Coveney, Richie Nimmo has recently offered an extended Foucauldian analysis of the politics of nutritional science surrounding one particular food product – milk – that accounts for the ethics and politics of human relations with other animals. In *Milk, Modernity, and the Making of the Human: Purifying the Social* (Nimmo 2010), Nimmo provides a genealogy of milk.

Genealogies, in Foucault’s sense of the word, are histories that oppose teleological or universalizing accounts of an historical phenomenon. Friedrich Nietzsche’s *Genealogy of Morals*, for instance, resists the view that morality has always been – and thus will always be – utilitarian. Foucault’s *History of Madness* and *Discipline and Punish* resist the views that the prison and the asylum, though recent phenomena, are the ends of a history of progress with respect to madness and crime. In each case, whether considering morality, madness, or crime, genealogies make the currently dominant views of these phenomena seem contingent and strange. Nimmo accomplishes a similar defamiliarization with respect to milk.

Although milk is now widely believed to be a normal, pure, healthy, and clean drink and an essential part of a balanced human diet, consuming dairy products derived from other mammals is in fact strange. After all, mother cows produce milk for baby cows, and if adult animals, including humans, do not drink the breast milk of their own species, why would it be natural or normal for adult humans to drink the mother’s milk of another species? Despite this fundamental oddness, drinking cow milk has come to seem like a natural thing for humans to do, and dairy is widely seen as an essential part of human nutrition or of the “food triangle.” Nimmo’s history shows how recent, contingent, and scientifically managed these intuitions are. Because milk spoils quickly and is easily contaminated, prior to the invention of railways and refrigeration, it was in fact very difficult for city dwellers to obtain milk that was not contaminated and spoiled. Because milk was closely associated with the nursing of infants, it was also seen as an infantile and feminine food, not a food for adults and especially not for men. Moreover, milk was (correctly) considered toxic, given that it carried tuberculosis from cows to humans. Health campaigns made matters worse for dairy farmers by advertising the fact that feeding cow milk to human infants was associated with high infant mortality rates, further entrenching the view that bovine milk was not meant for humans. Milk was also treated with suspicion as it was frequently watered down by farmers and merchants. Attempts to regulate the

butterfat content of milk met with a natural resistance, since it treated milk like a commodity that farmers rather than cows produced, when in fact butterfat content varies widely even with the milk of a single cow, and prior to scientific interventions into dairy farming, farmers could do little to assure the fat content of the milk they sold. Nimmo thus shows that milk was an exceedingly difficult food to standardize, to make safe, and to convince the public to drink. Far from being a natural beverage, an extensive disciplining of cows and farmers as well as extensive propaganda was necessary before the consumption of milk could be normalized.

In “Abnormal Appetites: Foucault, Atwood, and the Normalization of an Animal-Based Diet” (Taylor 2012), I, like Nimmo, have engaged with modern medical discourses on diet while accounting for the moral stakes of these discourses for other animals. This article considers the ways that both psychiatric discourses on mental health and medical discourses on nutrition have promoted a meat, egg, and dairy-based diet in manners that pass off social norms as science. It suggests that eating animals has become a norm such that vegetarianism is perceived as “abnormal,” and abnormality, as Foucault has shown (2003), has been associated by the psychiatric sciences with mental illness. This, in turn, makes vegetarianism an undesirable subject position to occupy. This argument is pursued through an analysis of literary representations of vegetarianism and psychiatric discourses on “Orthorexia Nervosa,” a newly coined eating disorder characterized by “obsession” with “righteous” eating.

Alimentary Identities and the Ethics of Eating

In “Foucault Goes to Weightwatchers,” Cressida Heyes agrees with earlier feminists that the practice of weight-loss dieting is well understood as an instance of disciplinary power or is a practice that women impose on themselves in their strivings to achieve a (hetero)normatively attractive and appropriately docile, feminine body. Heyes expands upon this argument, however, by observing the ways that dieting may not only be debilitating but may also increase skills and capacities, providing a sense of self-mastery

and achievement for the dieter. Heyes thus insists that women do not diet simply because they suffer from false consciousness, as a Marxist analysis would have it, but because they find the self-development and skill-cultivation aspects of dieting enabling. Heyes also observes that weight-loss programs are clever at picking up on these attractive aspects of dieting, deploying a language not so much of self-discipline as of self-care. In this way, the marketing strategies of dieting organizations resonate as much with the texts that Foucault analyzed in the final period of his writing as with his genealogical studies.

Despite making these points, Heyes ultimately argues that women should be wary of how the discourse of caring for the self is being used in the diet industry in the service of what remain highly normalizing practices. Heyes thus suggests that women should find activities that fulfill the need for the skill-enhancing and self-transformative aspects of weight-loss dieting, even while rejecting weight-loss dieting itself. One way that former weight-loss dieters (including dieters with eating disorders) have done what Heyes suggests is by taking on a non-normative diet such as veganism or raw foodism (see, for instance, Gena (2011)); in such a way, the dieter obtains the same sense of satisfaction from working on herself as she derived from weight-loss dieting, demonstrating self-mastery and developing new skills (such as new culinary skills), but her efforts are not doomed to failure – as is almost inevitably the case for weight-loss dieters (Heyes 2006, p. 145) – and are not “recycled back into disciplinary practices” (Heyes 2006, p. 138). On the contrary, the former weight-loss dieter who switches her alimentary regime to raw foodism or veganism cares for herself while defying social and alimentary norms such as speciesism.

Although, in her Foucault-inspired study of contemporary food culture, Elspeth Probyn has dismissed vegetarianism by saying it is a morality rather than an ethics in Foucault’s sense of these terms (Probyn 2000), Joseph Tanke and I have both disagreed, demonstrating that vegetarianism can indeed be understood as ethical practices of

self-care and moreover that morality and ethics need not be opposed for Foucault (Tanke 2007; Taylor 2010). Both authors note that vegetarians take on dietary regimes less to conform to universal moral codes than to become the kind of person they wish to be. Similarly, I have argued that resistance to vegetarianism is about aesthetics rather than a failure to be convinced by moral arguments. Vegetarianism – like other alimentary identities – is not something that one does, Tanke and I have argued, but is something that one is, or aspires to be, and that one makes of oneself through alimentary self-fashioning practices. While one can practice alimentary identities other than vegetarian ones, in “Foucault and the Ethics of Eating,” I argue that Probyn’s example of a carnivorous diet exemplifies what Foucault deems a “disgusting” ethics (Taylor 2010, p. 79); this is because, like the “virile” Greek ethics that depended on the submission of free women, boys, and slaves, eating animals fails to account for the pleasures of others.

Summary

This entry has examined a handful of statements that Foucault made about diet, as well as his suggestive discussion of alimentary dietetics. It has also presented some of the ways in which contemporary food scholars have taken up Foucault’s work in order to discuss a range of alimentary phenomena, including discourses of the nutritional and psychiatric sciences, the practices of vegetarianism and veganism, and weight-loss dieting.

Introduction

Debates between advocates of free trade and those who favor more protectionist policies seem particularly charged when the topic is international trade in food and agricultural products. World Trade Organization (WTO) discussions of the Doha Development Agenda (DDA) have been slowed in large part as a result of differences over global rules to govern agricultural trade. The agricultural provisions of the North American Free Trade Agreement (NAFTA) caused a great deal of consternation in all three countries, and many of the most intractable trade disputes brought to the WTO concern food and agricultural issues (Hobbs 2014; Levidow 2014a, b). The controversies surrounding free trade and protectionism for agricultural goods are part of wider debates about the effects of trade on economic well-being and the best way to organize global economic relations. For some, international trade

and globalization undermine the rights of workers, thwart efforts to protect the environment, and lower the prospects for economic growth and prosperity in low-income countries (see McArthur and Tucker 2010; Bybee 2008; Zepp-LaRouche 2008). From this perspective, it is not so much trade itself that is the problem, but rather the negative impacts of trade that are seen as unethical. Most economists, on the other hand, believe that international trade is a positive-sum game (if it were not the case that both parties benefit, they would have no incentive to trade) and that trade is essential for economic growth and development (see Shahbaz 2012; Arif and Ahmad 2012; Nannicini and Billmeier 2011; and Marelli and Signorelli 2011). From this perspective, free trade allows people to exercise basic freedoms and is therefore of direct ethical value. In addition, to the extent that trade contributes to greater well-being, it is also instrumentally valuable because of the consequences it generates.

Even for those who believe that an open world trade system is beneficial, however, disagreements about the details of such arrangements are common. When it comes to food and agricultural trade, the diverse points of view often lead to political polarization. The purpose of this article is to investigate arguments about free trade and protectionism with special emphasis on ethical issues related to international trade in food and agricultural products. The discussion begins with a review of the eighteenth and nineteenth century debates about the English Corn Laws which featured many of the arguments still invoked in modern discussions of free trade and protectionism. In the following sections of the article, an attempt is made to define both concepts more precisely and to introduce ethical arguments about free trade and protectionism in the food and agricultural sectors.

The English Corn Laws

One of the most famous debates about free trade and protectionism was occasioned by the British “Corn Laws” designed to regulate grain imports and exports. As far back as the 1600s, regulations

on grain trade had been implemented in an effort to keep prices high enough to satisfy farmers but not so high as to cause extreme hardship for the poor (Schonhardt-Bailey 2006). Cain and Hopkins (1980) argue that through the eighteenth and early nineteenth centuries, agriculture was the dominant economic sector in England and the landed gentry were successful in directing government intervention toward protection of their interests. At that time, England exported grain and the primary policy intervention was a type of export subsidy known as a “bounty.” In *The Wealth of Nations*, Adam Smith included a “Digression Concerning the Corn Trade and Corn Laws” in a chapter on the negative effects of bounties and the benefits of free trade (Smith 1976/1776, vol. II, pages 29–52). He argued that government interference with trade was the real cause of famines, food shortages, and high food prices. Grain was generally viewed as a “wage good” by the classical economists suggesting that the wages needed for workers to sustain themselves were largely determined by grain prices. Bounties and import duties, both of which raise domestic prices, thus tend to force employers to increase the nominal wage to maintain real subsistence wage levels in the manufacturing sector forcing them to charge higher prices for their output. For Smith, this made British manufacturing less competitive internationally.

By the beginning of the nineteenth century, England had become a net importer of grain and grain prices were being driven down by cheap imports. In 1815, a new Corn Law was enacted limiting grain imports when prices in England fell below a certain level (Schonhardt-Bailey 2006). In his *Essay on the Principle of Population*, Thomas Malthus (2004/1798) had already expressed disagreement with Smith noting that if economic expansion took place only in the manufacturing sector while the agricultural sector continued to generate a fixed amount of output, food prices would increase and real wages would fall. For Malthus, the only way to raise standards of living was to invest in agriculture. In a short essay on the 1815 Corn Law, Malthus (1814) returned to these themes, taking issue with Smith’s contention that while bounties or import

duties might raise the nominal price of grain, its real price would be unchanged as a result of the effects of the grain price increase on wages and the subsequent impact of higher wages on the prices of all other goods. Because real prices are what drive producer decisions, Smith argued that the trade policies would have no effect on grain output. For Malthus, allowing cheap imported grain would mean the decline of British agriculture and, because of the centrality of agriculture in the wealth of the nation, reduced economic growth and prosperity. Malthus recognized the disadvantages of import restrictions including inefficiencies in resource allocation, reduced international competitiveness, lowered population growth resulting from higher food prices, and the administrative costs of restrictive trade policies. He concluded, nevertheless, that the new Corn Law would benefit the English economy.

Malthus’s position was not shared by other economists of the time, most notably David Ricardo who provided one of the first full developments of comparative advantage, a concept that plays a central role in economic arguments in favor of free trade (Blaug 1978). In the first half of the nineteenth century, British agriculture experienced increased competition from imported grain and the land owners began to lose some of their political influence (Cain and Hopkins 1980). Schonhardt-Bailey (2006) traces the rise of the Anti-Corn Law League from its beginnings in 1836 to its eventual triumph in 1846, when the Corn Laws were repealed and free trade became the dominant ideology in England. The classical economists from Smith (1723–1790) to Karl Marx (1818–1883) saw economic output as the product of three factors of production, land, labor, and capital, each of which was associated with a particular social class, landlords, workers, and capitalists. In a sense, Malthus remained a defender of the landed aristocracy, while Smith and Ricardo pinned their hopes on the rising capitalist class and Marx, of course, thought of himself as the defender of the proletariat. The great debate over the Corn Laws in England pitted the interests of the landlords against those of the workers and capitalists, and whether one was a protectionist or an advocate of free trade

depended, at least in part, on which social class one favored and which interests would be advanced or impaired by international trade. Political and economic interests continue to play a prominent role in trade policy debates.

Free Markets and Free Trade

Most economic activity takes place in domestic markets which bring together local suppliers and consumers to engage in what Adam Smith described as the natural propensity of human beings to “truck, barter, and exchange one thing for another” (1976/1776, vol. I, page 17). International markets are an extension of domestic markets and the idea of “free trade” is similarly an elaboration of the notion of “free markets.” Most arguments in favor of free markets are based on the expected material benefits that arise from their greater efficiency compared to other economic arrangements (e.g., central planning) and the fact that the alternatives generally restrict individual rights and freedoms (Capaldi 2004). Buchanan (1988) reviews various ethical arguments in favor of free exchange and notes that these arguments are often intertwined with the efficiency claims. For example, it might be argued that the ethical dimensions of market systems derive from the fact that they allow individuals to freely express their preferences and to make use of their property as they wish (Gibbard 1985). Such arguments from individual freedom are tied to efficiency through the supposition that free individuals are capable of making choices that will lead to the best use of resources and the greatest economic benefit for themselves as well as for the society in general and that they will do so if given the chance. Sen (1985) agrees that markets may have practical value but finds suggestions that free exchange assures the exercise of individual rights problematic. After all, the extent of a poor person’s rights in free markets is clearly less than that of another person with greater resources, and markets are incapable of evening out such differences. If one believes that the rich person deserves her relatively greater opulence, it may be possible to see such market outcomes as justifiable. But, of

course, many wealthy people owe their good fortunes to luck, coercion, dishonesty, or theft rather than hard work and talent making it difficult to support the libertarian argument that whatever outcome is generated by the market is fair.

McClosky (2007), on the other hand, argues that markets promote individual virtues and a capitalist system based on free markets and private property not only makes everyone wealthier but also causes people to behave with greater virtue. McClosky is arguing against those who believe that there should be extensive market regulation, perhaps even the complete socialization or collectivization of markets, to prevent an unwelcome outcome such as highly unequal income distributions or environmental damage. It is important to recognize, however, that markets are never completely free of all regulation. In fact, an institutional framework that includes laws related to property rights, contracts, fraud, and so on is needed for markets to function at all (Acemoglu and Robinson 2012; Stiglitz 2013). Such laws can never be entirely neutral with respect to the particular individual interests that are favored making market institutions inherently political. Market anarchists believe that the political nature of governments’ control of the creation and enforcement of legal institutions makes them oppressive and argue that the state should be replaced by voluntary interactions such as those in unregulated markets (Molinari Institute 2013). Most, however, appear to believe that some set of legal institutions is a necessary prerequisite for a well-ordered market economy (Olson 2000). Acemoglu and Robinson show that the types of political and economic institutions that are established in a country are major determinants of whether people in that country prosper. The importance of institutions, including those that regulate commercial activity, brings the concept of free markets into question. If some regulations are necessary for markets to function, is there a clear place to draw the line between free and regulated (or “socialized”) markets?

The same question arises with respect to free trade. What kinds of institutions are compatible with free trade? For the Encyclopedia Britannica, free trade is synonymous with *laissez-faire*, an

economic system that permits only limited government interference with markets (<http://www.britannica.com/EBchecked/topic/218403/free-trade>). Other sources suggest that free trade requires only the absence of some specific set of trade barriers usually identified as import tariffs and export subsidies leaving open a wide range of economic policies that might be ruled out in a pure laissez-faire system (<http://www.merriam-webster.com/dictionary/free%20trade> or <http://glossary.econgurur.com/economic-term/free+trade> <http://glossary.econgurur.com/economic>). In general, these definitions all seem to point to import tariffs and export subsidies as the main protectionist policies that interfere with free trade, although in some cases other types of government interference such as exchange rate manipulation or government procurement practices are also included (http://www.auburn.edu/~johnspm/gloss/free_trade). They are generally silent, however, on government actions that may indirectly influence international trade (e.g., publicly funded research, subsidies to domestic producers). They would also seem to allow trade barriers to protect against harmful goods such as import restrictions on livestock products originating in countries where foot-and-mouth disease has not been eradicated. Finally, they do not appear to rule out measures to prevent private sector participants from behaving in ways that introduce inefficiencies into the world market through the exercise of monopoly power, for example, or through practices that would be illegal in the countries in which they are based (e.g., bribery). It appears that free trade policies may allow for a wide range of government market interventions including some that may favor domestic over foreign producers.

Most advocates of free trade would not call for the complete elimination of all public policies that may affect trade but rather would stress the benefits of reducing conventional trade barriers, a process known as “trade liberalization.” Palmetier (2005) reviews a number of ethical theories from utilitarianism to the non-consequentialist theories of Kant and Rawls finding that a liberal trade regime is compatible with all of these theoretical approaches. He notes that protectionism is likely

to violate individual rights and harm the least well off and points out that Kant saw trade as contributing to world peace (see also Moore 2003). Arguments against free trade often emphasize the unfairness to those who lose as trade is liberalized. Beghin et al. estimated that elimination of the US sugar tariff in 1998 would have led to losses to cane and beet growers and sugar processors in the United States totaling about \$1 billion compared with gains to US sugar consumers of \$1.9 billion. An additional advantage of such a change – note that the tariff has not been eliminated – would have been an increase in the world sugar price of about 13% to the benefit of sugar producers in low-income countries (Beghin et al. 2003).

Opponents of trade liberalization might argue that elimination of the tariff would be unfair because it would disrupt the lives of those who have devoted resources and effort to particular courses of action on the assumption that protection would remain in place (Palmetier 2005). In the sugar case, however, consumer gains would have been sufficiently large to compensate the growers and processors while still leaving consumers better off. Even if actual compensation is not made, one might question whether the *status quo ante* was fair in the first place because it generates benefits for some at the expense of others. Moreover, the policy does this in a way that is inefficient because total benefits are less than total costs. Providing an ethical justification for the US sugar policy would require an account of why the growers and processors deserve their gains and why it is fair for consumers to be required to pay for them. It might be possible to develop such an account, but the inconvenient fact that it would be cheaper to simply transfer a billion dollars to the growers and processors from general tax revenues rather than effecting this income transfer through the trade barrier would remain.

Palmetier (2005) points out that John Stuart Mill suggested compensating the landlords who lost from the repeal of the Corn Laws noting that even with compensation, there would be a net gain to England from the reform. It is almost always the case that trade liberalization leads to benefits that are greater than the costs so that those whose situation is made worse off could be compensated

for their losses. Of course, compensation is not always offered to those who lose from trade policy changes, and the specific effects such changes may generate will depend on the particular measures that are put in place. For example, trade agreements such as NAFTA or the Uruguay Round Agreement of the WTO often include provisions related to direct foreign investment, intellectual property, environmental concerns, and much more. Worries about such agreements may have less to do with tariffs and trade than they do with broader concerns about economic justice or environmental protection. In fact, opposition to the international economic organizations (WTO, International Monetary Fund, World Bank) often seems more an expression of uneasiness about capitalism and the undermining of national sovereignty than a worry about trade or international finance as such (Peterson 2014; Frank 2007). Proponents of free trade may also be using trade as a symbol to support their belief in the benefits of globalization. It sometimes seems that “free trade” has become a slogan that serves as shorthand for competing visions of the best way to regulate global interactions. Zepp-LaRouche (2008) speaks of the “...obvious bankruptcy of murderous free trade,” while Bhagwati (2011) claims that free trade not only brings greater prosperity but greater equality and world peace as well.

Protectionism

In many respects, protectionism is a more precise concept than free trade. The Encyclopedia Britannica defines it as the use of trade barriers to shelter domestic industries from foreign competition (<http://www.britannica.com/EBchecked/topic/479643/protectionism>). As in the case of free trade, exactly what constitutes a trade barrier is subject to debate. For example, publicly funded agricultural research can lead to innovations that lower costs for domestic producers giving them a competitive advantage vis-à-vis foreign firms. For this to constitute protectionism, however, foreign and domestic firms must be treated differently and this would not be the case if the cost-reducing

innovations are made available to all. Prior to the rise of free trade in the eighteenth and nineteenth centuries, the dominant economic policy in Europe, known as mercantilism, was highly protectionist. Mercantilist thinkers believed that the more gold a nation could accumulate, the wealthier and more powerful it would be. To increase the inflow of gold, mercantilists argued for increased exports and restrictions on imports. Imports of raw materials for use in manufacturing were permitted, but the overall goal was to use government policies to assure a trade surplus that would increase the nation's holdings of gold (Blaug 1978). As a general policy, mercantilism is obviously incoherent: it is impossible for all countries to have trade surpluses at the same time. Adam Smith and later economists did much to discredit this doctrine, but the view that exports are desirable because they earn money and create jobs while imports are undesirable because they cost money and displace workers lives on in many policy debates today (see Scott 2007).

At the same time, there is a kind of asymmetry in discussions of protectionism. The basic definition focuses only on protection of domestic firms and industries. Protecting the health of consumers, livestock, or ecosystems seems generally to be considered an appropriate use of government power, while protecting private industries is not. In its efforts to reduce protectionism, the WTO has become embroiled in a host of contentious issues related to ambiguities about the actual agents being protected by a particular policy. For example, as conventional tariff and nontariff trade barriers have been reduced, governments have increasingly turned to alternative measures such as technical standards that may have the same effect as the original trade barriers, but that can be justified on the grounds of consumer or environmental protection. The European Union (EU) defended its ban on imports of livestock products from animals raised with hormone supplements as a consumer protection policy, while Canada and the United States have always maintained that the intent of this policy is to protect EU livestock producers from foreign competition (Hobbs 2014). The WTO Agriculture Agreement includes provisions for the reduction

of agricultural subsidies that could lead to hardships for farmers in countries with agricultural sectors that are relatively uncompetitive internationally. Some of these countries (Japan, Korea, Switzerland, and Norway) note that farming generates external benefits (e.g., viable rural communities) for which farmers are not compensated arguing that domestic subsidies should be allowed under WTO rules to compensate farmers for these positive contributions (Adam 2014). Although policies to support the “multifunctionality of agriculture” would have the same effects as more conventional protectionism, they are thought to be justifiable not because they protect the domestic industry but because they represent legitimate compensation for services provided. It is notable that advocates for multifunctionality rarely draw attention to the negative impacts of farming (e.g., pesticide and fertilizer runoff, soil erosion, and reduced biodiversity) which may be of greater social value than the alleged positive contributions.

An early argument for protectionism embraced by Alexander Hamilton in the United States and Frederick List in Germany was that newly established industries, like children, needed protection until they are mature and able to compete with established industries overseas (Melitz 2005). Melitz shows that under fairly restrictive conditions, national welfare may be advanced by protecting infant industries but argues that only new industries with the clear potential to be able to achieve the needed efficiencies rapidly should be considered for this protection. In many cases, government protection has resulted in industries that remain inefficient unable ever to compete without the protective trade barriers. Many developing countries pursued industrialization strategies based on import substitution, a policy that restricts imports to allow a domestic industry to become established without being undermined by foreign competition. While these strategies did contribute to some industrialization in low-income countries, they have not proved to be effective strategies for industrialization, growth, and development because domestic markets are usually too small to support large-scale industries. The typical effect has been higher

prices for consumers, lower quality consumer and intermediate goods, industries dependent on government support for their continued existence, and severe balance-of-payments crises as resources are diverted from export industries in which the country has a comparative advantage to uncompetitive domestic firms.

A common rationale for protectionism is that it supports domestic employment. Shortly after the 1929 stock market crash, the US Congress raised tariffs in a misguided effort to preserve jobs. The Smoot-Hawley tariff of 1930 had little effect on employment as other countries retaliated by raising their trade barriers so that US imports and exports both fell (Irwin 2002). Despite much evidence to the contrary, many still believe that imports cost jobs and call for trade barriers to protect domestic employment, particularly in times of economic downturn. The Trans-Pacific Partnership (TPP) signed in early 2016 faces a difficult ratification process as politicians and many others in the 12 countries that are party to the agreement have spoken out against it. Another important regional trade agreement, the Trans-Atlantic Trade and Investment Partnership (TTIP), is also controversial. It turns out, however, that trade barriers can actually cost the economy jobs by raising the price of imported goods that are inputs for other industries. US sugar prices are usually higher than world prices as a result of the tariff making US candy producers and other industries that use sugar as an input less competitive. Irwin (2002) cites the example of a candy company in Chicago that was forced to move its production facilities to Canada because of the high US sugar prices at the cost of 3,000 US jobs. There is virtually no evidence that protectionism can lead to a net increase in jobs or that it lowers unemployment rates, although trade liberalization can cause disruption in industries that are not globally competitive.

In recent years, numerous individuals and groups have responded positively to calls to slow globalization often seen as a process that causes harm to the environment, workers' rights, economic growth and development in low-income countries, traditional food systems, and much else. As a central component of

globalization, trade is often seen as particularly suspect because of its ties to commercial activities and global capitalism. Irwin (2002) suggests that the underlying concern of many of the groups opposing trade is actually their distaste for modern, industrial capitalism seen as driven by the profit motive rather than by more noble objectives such as environmental sustainability or poverty alleviation. As the world economy has become more turbulent, some economists have embraced criticisms of trade and globalization primarily because of the way they are being managed (Stiglitz 2013). Joseph Stiglitz, 2001 Nobel Laureate in Economic Sciences, and others have noted that the benefits of liberal trade are often not widely dispersed in countries with deficient economic and political institutions with the result that free trade may actually make the poor worse off. Stiglitz does not oppose international trade as such but rather sees the way global markets are managed by firms and governments working through international trade agreements as biased in favor of large corporations and wealthy people in high-income countries. Stiglitz (2015) is particularly concerned by provisions in TPP and other trade agreements allowing private firms to challenge government regulations through “investor-state dispute settlement (ISDS)” processes. These concerns do not so much represent a call for protectionism as recognition that markets will always be regulated in some fashion and that the particular regulations chosen can be structured to favor certain groups at the expense of others. For Stiglitz, the way current global institutions are set up is wrong because they favor the wealthy while harming the poor. Some might argue for trade restrictions on the grounds that global institutions will always be established by those with economic and political power so that international trade cannot but be biased against those who lack the power to influence the rules of the game.

Conclusion

There is a long history of conflict between those who believe that free trade is essential not only for economic prosperity but also for the exercise of

individual freedoms and those who see international trade as a threat to their personal economic interests or traditional ways of life. Those in the latter group often feel that measures to protect domestic industries from foreign competition are necessary to maintain employment and to prevent global interference with vibrant local communities. Protectionism is always about protecting particular groups from the consequences of international trade and, as with earlier debates about the British Corn Laws, whether one favors or rejects protectionism in a particular case depends on beliefs about how favored groups or causes, including those concerned with such considerations as the environment or social justice, will be affected by trade. In general, protectionism is an inefficient way to direct economic or other types of benefits toward favored groups or causes because it generates broad social costs that are almost always greater than the value of the benefits diverted to the favored group or cause.

For others, the freedom to engage in economic activity is part of individual entitlements, and protectionism violates this basic right. Beyond the importance of trade for individual freedoms, open markets tend to lead to beneficial consequences for economic growth and development and these effects have given rise to calls for free trade. But the concept of free trade is ambiguous because markets are always regulated in some fashion. If they are not regulated by governments, they will be regulated by private firms or organized crime (see Olson 2000). Assuming that governments and international organizations establish the rules and regulations governing international markets, it may not always be entirely clear why some kinds of protectionist policies (e.g., protecting consumers from harmful or dangerous products) are deemed legitimate, while others are not. The WTO and other international organizations often must confront such questions particularly when it is unclear whether a protectionist trade measure is aimed at preventing harm to consumers or the environment or, on the contrary, is really designed to shelter firms from foreign competition. Finally, the particular institutions chosen to govern global markets influence the distribution of economic costs

and benefits among various agents. Some institutional arrangements may be deemed unethical because they violate common norms of distributive justice. In such cases, however, it could be argued that it is really the institutions that are unethical rather than international trade per se.

Functional Foods

Introduction

In the most basic sense, all foods are functional. Specifically, all foods serve some function in the body: they provide energy, nutrients, micro-nutrients, water, or fiber necessary to maintain and promote life. However, *functional foods* are a subset of foods – one could also think of them as a category of foods – that are considered by many to have properties that make them especially potent in promoting maintenance of a healthful life. These foods are typically characterized by the addition or enhancement of a biologically active ingredient understood to promote health and often appear to dance between food and medicine.

A variety of political factors, social trends, and technological innovations have shaped the creation of the contemporary category of functional foods. This food category first originated in Japan during the mid-1980s as part of a state-sponsored research project that sought to analyze, characterize, and improve the nutritive properties of foods. That research resulted in a new, state-recognized,

state-regulated, and state-defined food category. Unlike traditional foods, or even fortified foods, these new functional foods were created and engineered with the express aim of addressing specific health concerns.

In many ways it is easier to give examples of functional foods than to define them. One familiar example for much of the United States and Europe is margarine with added phytosterols (compounds isolated from plants). On-package copy and advertising inform consumers that consumption of this product can help lower cholesterol. This product's existence is made possible by the confluence of a variety of governmental regulations, technological innovations in biomedical and agricultural research, public and private institutions, and corporations. The joining together of these disparate groups highlights the variety of ethical concerns surrounding functional foods. This entry first briefly situates the development of the concept of functional foods, discussing the difference between historical understandings of foods as functional and the contemporary conception of functional foods. Next, this entry examines the variety of ethical concerns surrounding functional foods. These concerns include issues of:

- Production (How are these foods produced?)
- Regulation and communication (What impact does government regulation have?)
- Access (Who has access to these foods?)
- Efficacy (Do these foods work?)

Situating Functional Foods

Humans have long understood foods as promoting health or preventing illness. For example, Galen and his followers viewed foods as regulating the humors of the body, proscribing specific diets for specific personalities and ailments. Followers of Paracelsus believed that nature's bounty of plants, minerals, and animals contained hidden remedies for disease. Nineteenth- and twentieth-century discoveries of vitamins demonstrated that unseen components of foods could dramatically affect human health. Functional foods build on these ideas, with a centralizing belief that one

can consume specific foods with specific components for specific ailments, as either curative or preventative.

However, unlike previous iterations of the food as medicine trope, functional foods are built on twentieth-century technological innovations in agriculture, biological medicine, food production technologies, and new forms of legal regulation. Functional foods make explicit an underlying change in the conception of food itself, from that of a whole to that of something built up of constituent parts (Mudry 2009; Scrinis 2008). For some, this marrying of the natural and technological into innovative food forms calls for additional scrutiny. How do we know that these foods will not harm us? How are these foods being produced, and at what costs? For others, the new regulatory frameworks that allow food corporations to take up the task of educating consumers about their bodies and health call for further examination. Are these regulations adequately protecting consumers, or are they promoting big business and quarterly profits without regard to consumer health? Finally, others question the ways that these health-promoting foods are available, noting the premium prices often attached to these foods. Are these foods recreating and expanding the health gaps between the haves and the have-nots?

Producing Functional Foods

Functional foods are founded on technological innovation. Without the analytical technologies of the engineering, chemical, and biological disciplines (e.g., physical chemistry, organic chemistry, cellular and molecular biology, clinical medicine, packaging technologies, food science), these foods cannot exist. These scientific approaches make possible the extraction and analysis of plant and animal-based compounds. In general, compounds are analyzed for potential biological activity in the body, either by academic scientists working at universities under public or private funding or by in-house or external laboratories working for the pharmaceutical or food industries. Although taken alone these technologies exist in a sort of ethical non-place (i.e., they

are neither good nor bad), these technological innovations raise a variety of questions. For example, how is technological innovation applied to biological organisms? What role do genetic engineering and modification play in this creation of new foods? Who funds this innovation? Who ultimately profits from it?

From the functional food perspective, genetic engineering and modification can facilitate the production of biologically active compounds – molecules that “do stuff” in the body. Genetic engineering often seeks to either (1) increase (or decrease) naturally occurring compounds or (2) introduce new genes into already existing systems. These transformations carry a (perhaps undeserved) heavy burden of risk – what unintended consequences accompany introducing new genes into a species? In addition to the short-term benefits of increasing production of certain compounds, what other sorts of larger ecological risks may be present? These could include loss of native plant populations and increased risk for plant disease due to accidental activation or suppression of other genes. At the same time, genetic engineering offers a variety of potential benefits: decreased use of pesticides, new business opportunities, increased crop value, positive changes for human health, and beyond.

Not all functional ingredients come from genetically engineered sources. Many are naturally occurring – familiar examples include omega-3 fatty acids from fish oils, phytosterols found in soy, and flavanols found in grape skins. Naturally occurring functional ingredients are especially exciting in that they potentially open new supply chains that can transform rural economies. A notable recent example is the increasing interest in the beneficial ingredients found in the açai fruit. The burgeoning popularity of açai has transformed this previously “unknown” fruit: once gathered for a local population, the rise in popularity has pushed both the people who produce it and the fruit itself into worldwide market transactions and power flows. Yet as these local farmers see an increase in access to international markets, they are also faced with competition from outside investors. The example of açai reminds us that many of the functional ingredients

identified and promoted come from third-world countries or from at-risk sources, a haunting reminder of colonial extraction economies and the more recent biopiracy debates of the late 1980s and 1990s.

When asked to give examples of familiar functional foods, one likely responds with examples that are highly processed and intensively packaged. Processing can provide health benefits by making previously unavailable nutrients available. Yet it may also harm human health. Despite the considerable research into the nutritional effects of consuming certain “functional” ingredients, the reality is that we still poorly understand what a food molecule does within its larger native food matrix. The functional food paradigm of isolating compounds, reducing food down to its bare components, and remaking it into something that offers “more” can also remove beneficial micronutrients that exist in the native food. Thus, by isolating and extracting only the compounds identified as beneficial – a process which prioritizes only those compounds that can be “made visible” via measurement and testing – the current functional food production paradigm also risks the loss of other health-promoting compounds from diets that once focused on consuming whole foods.

Packaging allows producers and marketers to communicate the health benefits of functional foods to consumers. While protecting foods and prolonging shelf life, packages also threaten both human and ecological health. As recent studies of leaching of compounds from plastics previously considered “inert” demonstrate, packages themselves can affect human health in unwanted ways while also contributing to an ever-growing trash problem.

Regulating Functional Foods

For industrial producers, the ability to communicate health-related claims on packages and in advertisements to consumers is a key driver for making functional foods. Some states strictly monitor and limit food labeling and health claims, others allow a variety of claims; these regulations

directly affect the market presence of functional foods. Changes to the regulatory framework around food labeling and health claims in the United States provide an especially potent illustration of how state regulation encourages or restricts functional foods.

A variety of laws influence the marketing of functional foods in the United States. The door to functional foods, as we know them, opened during the deregulatory Reagan era. In 1987 the Food and Drug Administration (FDA) began allowing companies to make health claims without first participating in premarket review (Heller 2005: 171). The number of claims on food labels exploded. Understandably, this freedom to make health claims on food was a marketer's dream and a consumer advocate's nightmare. The October 9, 1989, *Business Weekly* cover summed up the era with the words "Can Corn Flakes Cure Cancer? Of course not. But health claims for foods are becoming ridiculous." By 1990, Congress responded to calls for reform from consumer advocates, industry players, and regulators by passing the Nutrition Labeling and Education Act (NLEA). The NLEA permits health claims as long as those claims "describe a relationship between a food substance and a disease" and carry the backing of "significant scientific agreement among qualified experts" regarding the validity of the claim (21 CFR §101.14). NLEA-approved claims require significant research time and money: for example, 43 human clinical trials examining the role of soy were included in the petition for the soy health claim (ADA 2009). Currently the FDA only approves 12 types of food claims. For example, the claim found on a 2009 Bolthouse Farms Heart Healthy Pear Merlot Apple Juice Blend label that "Barliv barley betafiber is a natural source of beta-glucan soluble fiber that helps support heart health with 3 g per day, when consumed as part of a low fat, low cholesterol diet. This bottle of juice contains 1.4 g of beta-glucan soluble fiber (0.75 g per 8 oz serving)" is NLEA approved under 21 CFR §101.81, Soluble Fiber from Certain Foods and Risk of Coronary Heart Disease.

Implementation of NLEA slowed the frenzied business of making health claims on food to an

ordered trickle between 1990 and 1994, with many companies removing claims completely. However, in 1994, the US Congress passed the Dietary Supplement Health and Education Act (DSHEA). DSHEA threw open the door for functional foods by allowing structure/function claims. Unlike claims permitted by the NLEA, claims for dietary supplements do not require the difficult-to-achieve status of "Significant Scientific Agreement," nor do they require prereview by the FDA. Instead, dietary supplements are allowed to make descriptive claims about how a component of a food, or an ingredient added to a food, may affect the body's structure or functions as long as the claim does not link consumption of the food with treatment of disease. These "structure-function" claims allow significant latitude in packaging and media communication as long as the disclaimer "these claims have not been evaluated by the FDA" is on the package.

The 1997 Congressional approval of the Food and Drug Administration Modernization Act further muddled the regulatory picture. This act permits the usage of unreviewed health claims as long as such claims are based on the current views expressed by the National Institute of Health, Centers for Disease Control, or National Academy of Science. Five years later, in 2003, the FDA loosened regulations by allowing qualified health claims. Qualified health claims, like DSHEA claims, do not meet the requirement of significant scientific agreement. Examples of qualified claims include claims linking green tea and risk of cancer and linking omega-3 fatty acids with a reduced risk of coronary heart disease. Currently, functional foods, depending on the health claims made and ingredients used in their manufacture, fall into the following categories: foods, foods for special dietary use, foods that make health claims, dietary supplements, drugs, and medical foods. Since 2003, this wide swath of regulatory niches allows US manufacturers significant wiggle room in how they both label and market their products.

In contrast, recent European Union regulatory shifts have made marketing of functional foods much more difficult. The European Commission estimates that approximately 44,000 claims were

initially submitted in 2008 when the commission began reviewing claims. That list was condensed to 4,600, which the European Food Safety Authority, EFSA, extensively reviewed. On May 16, 2012, the EFSA announced approval of 222 claims and the requirement that all claims not under review or authorized by the new regulation be phased out by the end of 2012 (European Commission 2012). This list is much more expansive than the US list of qualified health claims; however, in requiring that all claims undergo review, the EU has created a significant dissuasion from spurious claims. Unfortunately, this legislation and the language around the process obfuscate the behind-the-scenes political negotiations and scientific uncertainties implicit in such legislative action, potentially leaving consumers with the impression that they no longer need to critically think about the claims on packaged foods in Europe (Nestle 2007).

The differences between the US and EU approaches to regulating functional foods highlight the role that marketing plays in making a food functional. A variety of critics of functional foods note that it is marketing that ultimately transforms foods into functional foods. They argue that without the communication between package designers, graphic artists, and advertising and marketing groups, functional foods cannot exist (c.f. Scrinis 2008). This view fails to account for the variety of definitions available for the term, excluding to some extent discussion of lay appropriation of the term “functional food” or the ideas implicit therein that appear in personalized approaches to conceiving of and understanding food. However, their critiques powerfully focus a critical gaze on the role that regulatory mechanisms play in containing communication about functional foods.

Despite the underlying foundational concept of functional foods as foods with purpose, definitions from both governing bodies and professional groups vary. For example, in 1999 a European Union Commission defined functional foods as foods that:

... [are] demonstrated to affect beneficially one or more target functions in the body, beyond adequate nutritional effects, in a way that is relevant to either

an improved state of health and well-being and/or reduction of risk of disease. Functional foods must remain foods and they must demonstrate their effects in amounts that can normally be expected to be consumed in the diet: they are not pills or capsules, but part of a normal food pattern. (European Commission 1999:S6).

Through this definition, EU regulators attempt to clearly mark the boundaries between foods and medicine. In contrast, the United States has no codified definition for functional foods. That work is currently left to professional groups. For example, the American Dietetic Association (ADA) argues that all foods are, on some level, functional, because all foods provide the body with necessary nutrients or other molecules that contribute to the body’s ability to survive (2009). However, for the ADA, functional foods “move beyond necessity to provide additional health benefits that may reduce disease risk and/or promote optimal health. Functional foods include conventional foods, modified foods (i.e. fortified, enriched, or enhanced), medical food, and food for special dietary use” (2009). An expert panel organized by the Institute of Food Technologists (IFT), a US-based professional group with an international membership, defines functional food as:

... foods and food components that provide a health benefit beyond basic nutrition (for the intended population). Examples may include conventional foods; fortified, enriched or enhanced foods; and dietary supplements. These substances provide essential nutrients often beyond quantities necessary for normal maintenance, growth, and development, and/or other biologically active components that impart health benefits or desirable physiological effects. (2005: 6)

Although Japan has defined functional foods, use of the definition was eliminated in 1991 in favor of the Foods for Specified Health Uses (FOSHU) system. The FOSHU system regulates functional foods separately from pharmaceuticals (Heasman and Mellentin 2001).

These definitions reveal a variety of tensions – the EU definition points to a need to define food itself, implicitly questioning when food ends and medicine begins. Both the ADA and IFT definitions allow conventional foods, such as fruits and

vegetables, functional status yet point to a reductionist view of foods made up of essential nutrients that may be stripped from an original source (such as conventional foods) and added to other foods (such as fortified, enriched, or enhanced foods). It is precisely this reductionist approach to foods that allows functional foods to claim to go beyond adequate or basic nutrition and beyond necessity to a realm where food can do more than just nourish – it can potentially prevent or heal.

Unfortunately, the claims making central to marketing of functional foods creates a power imbalance between the producer/marketer and the consumer (Liakopoulos and Schroeder 2003). Lax regulatory regimes exacerbate this imbalance. No matter the regulatory climate, the burden of evaluating the truthfulness of claims ultimately falls to the consumer (Kaplan 2006). A difficult task under any circumstances, this burden of evaluation is rendered even more problematic by a general lack of scientific literacy among most populations, limited access to study results, and sensationalized media reports.

Accessing Functional Foods

Functional foods are, at least upon initial introduction to the market, primarily foods for health-conscious consumers with disposable income. This is reflected in the way these foods enter the market. Market entry for functional foods can be split into two routes of entry: that of a small entrepreneur doing product development and market introduction or that of a large food company introducing a functional food throughout its regional or national distribution chain. Given the cost of product development, many large food companies have chosen to either adopt a “wait, see, and buy (from another company)” approach or choose to develop functional foods based on already existing functional ingredients available from suppliers. Both approaches outsource responsibility for testing the efficacy of functional foods or ingredients, a step that ultimately protects producers more than consumers.

The first approach, that of the small entrepreneur, results in functional foods being primarily

introduced in highly specialized stores that sell these products at premium prices. Many of the successful functional foods on the market are sold in single serving sizes (nutrition bars, beverages, yogurts) that are not conducive to feeding a larger group. There are exceptions: pastas with added omega-3 fatty acids, for example, are routinely sold in family-friendly package sizes. However, the emphasis on individualized consumption highlights contemporary concerns with the ways that governments have shifted responsibility for health care away from a larger social safety net and onto individual consumers (Holm 2003). Assuming these foods work as stated, those who have the consumer power to access this type of individualized health care will potentially live longer, more productive lives (Landecker 2011). In contrast, those without the financial resources to access functional foods will be left behind, further increasing the gap between the haves and have-nots (Schroeder 2007). This split between haves and have-nots is reflected in the notable lack of publications on functional foods outside of the major markets of Japan, the United States, and Europe. Despite the potential for both huge market growth and for significant consumer abuse, minimal academic attention has been paid to developing markets such as Latin and South America and Africa (for exceptions, see Hasler 2005). Further complicating the haves/have-nots equation, many of the “hottest” ingredients used to make functional foods come from third-world locales. As demand for these raw ingredients and supplies grows, local ability to access these health-promoting foods often diminishes.

On the other hand, transnational corporations have the power to positively affect the health of large swaths of the world’s population through functional foods. For example, functional foods targeted to third-world markets could deliver needed micronutrients or antiparasitic compounds to at-risk populations through already existing distribution chains of companies with a global presence. At the same time, the potential lack of regulation as these foods circulate throughout different regulatory regimes raises additional concerns about consumer protection.

Finally, much of the “pipeline” that leads to the creation of functional foods is supported by publicly funded research. The knowledge gained from these studies is often transformed into patents for isolated ingredients or testing technologies that regularly make the jump into private corporate hands, leaving potential public users unable to access or use the knowledge their tax dollars helped fund. This distillation of public money into private profit is echoed in many debates about pharmaceuticals, hybrid seeds, and engineering technologies (Kloppenburger 1988).

Evaluating Efficacy

Do functional foods work the way they claim they do? This question underlies all the debates about functional foods, from the question of definitions to regulations to marketing. Evaluating the effectiveness of functional foods in affecting human health requires significant time, money, and access to study subjects willing to follow the strict diets necessary for attempting to evaluate any food. As many have pointed out, the clinical trial model, developed for testing pharmaceuticals, often obfuscates more than it enlightens when it comes to testing foods (c.f. Richardson 2012). Although specific functional ingredients can be tested outside of a food matrix, any results must be examined suspiciously given the possible interfering or synergistic nature of other foods consumed in a diet.

This inability to demonstrate effectiveness via the clinical model, especially when coupled with the short life span of many industrially produced foods (most new food products fail within the first year of introduction to market), creates an economic push for many functional food manufacturers to market their foods as dietary supplements. As discussed above, the intrinsic differences in review processes between foods and dietary supplements, especially in the United States, mean that the labels of foods marketed as dietary supplements do not undergo the same review by regulatory agencies that other foods do. Unfortunately, this creates additional opportunities for unscrupulous, unfair, or misleading

marketing, a condition that is only exacerbated in countries with weak regulatory bodies (an area that could benefit from additional academic inquiry).

With few exceptions, most functional foods remain fairly understudied in the clinical setting. This raises the additional question of evaluating safety: are these foods safe for consumption? As with all foods, and especially with dietary supplements, one must ask to what extent manufacturers follow safe practices, especially in developing countries.

Summary

Functional foods offer the exciting possibility of promoting human health. Yet they simultaneously pose a threat to consumers through misleading marketing and inadequate regulatory protection. If efficacious, functional foods, through their premium price point and limited distribution, reinforce already existing social inequalities.

Introduction

Though notoriously hard to define, this entry adopts an understanding of functional foods as food products marketed for their health benefits.

This definition includes products as diverse as calcium-fortified orange juice, omega-3-enriched eggs, and cholesterol-reducing margarine. The concept of functional foods encompasses both the application of nutritional science and technology to the development of food products and ingredients designed to deliver certain health benefits and the unprecedented level of marketing of food, nutrition, and health required to promote the concept (Heasman and Mellentin 2001). It is closely tied to the ability of manufacturers to make direct or implied health claims on product labels and in advertisements, an area of global regulatory friction. Market actors, not public authorities, drive the development of such products. While functional food commodities may reflect public health priorities, they are not developed as part of public health policy (Holm 2003).

Conventional nutritional wisdom holds that there are no bad foods, only bad diets. A good diet includes variety, balance, and moderation and is one component of determining health on both an individual and population-wide basis. Functional foods challenge this understanding of the relationship between food, diet, and health. Further, functional food science blurs the boundary between drugs and food by proposing the use of technologically altered foods in disease treatment and prevention. Critics suggest that functional foods represent an understanding of the food supply as a commodity rather than a public health resource (Holm 2003). Such concerns illustrate that the regulation of how functional food products are developed, distributed, and marketed is a global public health issue.

This entry begins with a discussion about the contentious definitions of functional foods. It then traces the historical development of technological foods, from early fortification initiatives to the current market for nutritionally oriented products. Functional foods are situated within the social context of medicalization and individualization of public health and the political context of deregulation regarding the use of health claim. Criticisms from both public health and ethical perspectives are discussed, and prospects for the future development and regulation of functional food products are evaluated.

Varying Definitions of Functional Foods

One of the problems in evaluating and regulating functional foods is a lack of agreement regarding their definition. The International Food Information Council, an industry-supported body, defines functional foods as “foods that provide health benefits beyond basic nutrition” (Katan and Roos 2004). Yet the idea of “beyond basic nutrition” is problematic, since all foods can be argued to demonstrate targeted biological action on some function of the body in addition to providing nutrients. Also, some organizations, such as the American Dietetic Association and Health Canada, include whole foods alongside fortified, enriched, and enhanced processed foods in their definitions of functional foods (ADA 2009; Health Canada 1998). This understanding serves to confuse things further, blurring the boundary between natural and processed foods from a nutritional standpoint and making the category of functional foods nearly impossible to measure.

A clearer definition of functional foods takes into account the reality of the marketplace, in which functional foods are viewed as commodities that are closely tied to the use of health claims. Katan and Roos define functional foods as follows: “A functional food is a branded food which claims explicitly or implicitly to improve health or well-being” (Katan and Roos 2004, p. 370). This definition is useful both in terms of measuring the monetary value of the functional food market and in establishing regulations regarding the use of health claims. However, the intimate link between functional food development and marketing, significant scientific activity examining the food-health-nutrition connection, and a profit-driven global food industry is difficult to encompass in a single definition of the term.

Scrinis has suggested that the term “functional foods” is contentious and misleading and that it be abandoned altogether. He argues that there are no clear criteria for distinguishing functional foods from other foods, as all foods impact the health of the body. Further, he argues that the application of the term to both conventional and modified foods encourages a reductionist view of food and nutrition, in which a food’s value is determined by its

nutrient content alone – a concept he refers to as “nutritionism.” According to this paradigm, an orange and a soft drink with the same vitamin C content would be viewed as nutritionally equal. He therefore proposes three alternative terms: “functionally marketed foods,” “nutritionally marketed foods,” and “nutritionally engineered foods” (Scrinis 2008). Such categories would allow a more transparent discussion and evaluation of functional food products. This entry continues to use the term “functional foods” in accordance with the literature but limits its definition to those foods marketed using a health claim.

Historical Background: Diet, Disease, and Public Health

The concept of functional foods as those foods designed and marketed specifically for a particular health benefit was first developed in Japan in the 1980s, as the Japanese government sought to address rising healthcare costs for an aging population. Japan remains the only country to recognize functional foods as a distinct legal regulatory category, although in 1991 the term “functional foods” was replaced by “foods for specified health use” (FOSHU) (Heasman 2008). However, the public health climate of the United States throughout the latter half of the twentieth century provided a hospitable environment for the introduction of the concept. Using a definition of functional foods “by which ingredients with an additional health-value have been added to foods (and this is announced to the consumers),” the functional foods market in the United States is now the world’s largest (Menrad 2003, p. 181). It is therefore worthwhile to explore the historical development of technological foods in relation to public health in the United States.

Fortification as Public Health Policy

Functional foods as commodities have developed in a context in which fortification has long been accepted as a public health measure. From a purely technological perspective, functional

foods are not that new. Fortification – the addition of vitamins or minerals to processed foods – has been used as a public health intervention since the early 1900s, when Europeans began adding iodine to table salt in order to prevent goiter. The introduction of iodized salt in the United States in 1924 effectively eliminated iodine deficiency as a public health concern and gained favor for further fortification measures. By the end of the 1950s, fortification of many commonly consumed staples was a common public health practice. *Standards of identity* for enriched flour and other grains were established, ensuring that all such designated products were fortified with particular nutrients considered to be most lacking in the American diet. The Federal Department of Agriculture (FDA) backed these measures. They were considered good public health initiatives because they offered a way in which to improve nutrient intakes – especially among low-income populations in which deficiencies were most common – without the expense or effort of education campaigns or changing population-wide dietary habits (Nestle 2002).

With fortification firmly entrenched as public health policy, food manufacturing companies began to recognize the potential of voluntary fortification for increasing profits. Adding vitamins and minerals to processed foods cost very little, yet enabled retailers to sell fortified products at much higher prices than standard products. By 1984, 92% of breakfast cereals were voluntarily fortified (Nestle 2002, p. 305). Nutrient deficiencies were no longer a widespread public health concern, but the increased incidence of chronic diseases including cancer and heart disease provided incentives for companies to fortify products with preventative nutrients such as antioxidants. Critics questioned whether improving the diets of Americans one nutrient at a time made good nutritional sense, but it did not matter: it made good business sense.

Throughout the 1980s and 1990s, the US government encouraged the food industry to develop products in line with particular public health goals. For example, the 1988 Surgeon General's Report on Nutrition and Health called upon manufacturers to create foods lower in fat and higher

in fiber, while the 1990 Public Health Service's 10-year plan explicitly requested that food processors double the number of products lower in fat available on the market. In tandem with these requests, legislation was introduced that enabled manufacturers to make some claims regarding nutrient content, health benefits, and disease prevention on product labels. As such, companies rushed to develop products with the specific intent of marketing them for their health benefits.

The Healthy-Eating Revolution

Both the increase in nutritionally oriented food products and the active role of the government in encouraging their development are results of what Heasman and Mellentin (2001) call the “healthy-eating revolution.” Starting in the 1950s, researchers began to draw a connection between overconsumption of certain nutrients and an increase in degenerative diseases. Scientific consensus regarding the unbalanced nature of the Western diet grew rapidly, and by the 1970s, the need for dietary reform in the developed world was widely accepted as a public health issue. Government intervention in the healthy-eating revolution largely took the form of the development and dissemination of dietary goals and guidelines. Although these have changed in both language and content since their introduction, the key principles advocating a diet of moderation remain the same. A healthy diet is defined as one that is high in fruits, vegetables, and grains, that includes moderate amounts of fish, lean meat, and low-fat dairy products, and that is low in fats (particularly saturated fat), sugar, and salt. By the 1990s, the central ideas of the healthy-eating revolution were widely accepted by policy makers, nutritionists, and the public.

From a policy standpoint, these actions represented “a change in emphasis from micronutrient deficiency to one where food itself became associated with chronic disease” (Heasman and Mellentin 2001, p. 59). Such a shift implied dramatic economic implications to those sectors of the food and agriculture industry whose products were given the guilty verdict. To adhere to healthy

diet recommendations, people would need to cut back on meat, eggs, dairy, and processed foods high in salt, sugar, and fat. The first response of certain segments of the food industry was to attempt to discredit the new nutritional paradigm, but as it became clear that the healthy-eating revolution was here to stay, companies developed new tactics. Still observable in the marketplace today, “the commercialization of the healthy-eating revolution is expressed in the thousands of fat-reduced, low-fat, fat-free, sugar-free, sugar-reduced and high-fibre product launches in the food and health marketplace since the 1980s” (Heasman and Mellentin 2001, p. 60).

While the healthy-eating revolution laid the groundwork for the rise of functional foods, the two movements differ significantly. The healthy-eating revolution was publically driven, “officially” promoted, and aimed to change diets through public policy, while the functional foods concept is industry driven, commercially promoted, and aims to change diets through marketing (Heasman and Mellentin 2001, p. 57). They also differ ideologically: instead of focusing on the whole diet and offering population-wide dietary goals, functional foods focus on single products or ingredients and promote individual outcomes. The tension between the two concepts is felt in resistance from public health authorities and consumer advocacy groups.

The Social Context: Conflicting Public Health Paradigms

Functional food commodities have gained momentum against a backdrop of particular underlying assumptions about the best way in which to deliver public health initiatives. Lawrence and Germov (1999) categorize public health interventions as falling under two distinct paradigms: the health promotion paradigm, which focuses on promoting the health of an entire population, and the medical paradigm, which focuses on reducing risks and treating illness in individuals. On a population-wide basis, health is a product of a combination of social, economic, and cultural determinants. Interventions intended to

promote the health of a population as a whole must address these underlying circumstances in which health is created. Interventions designed to reduce disease in individuals aim to foster lifestyle changes, including dietary behaviors. Both paradigms can be useful in different scenarios and can be used together. However, in reality, the medical paradigm dominates in the delivery of healthcare. It is in this context that food has come to be “regarded as a commodity that may be modified to assist the dietary reform process” (Lawrence and Germov 1999, p. 57).

Also shaping public health education policy in the United States are the complementary ideologies of rational individualism and economic liberalism. Rational individualism assumes that when given proper information, the individual will make the best choice for her health, while economic liberalism assumes that the delivery of the health message is the only government requirement, leaving it to the individual to make lifestyle changes accordingly (Lawrence and Germov 1999). Further underpinning the health education approach is the belief that the consumer will respond to health education messages and make the best choice for her health – an assumption that neglects the myriad other factors that influence food and lifestyle behaviors. An alternative social viewpoint is that of collectivism, in which emphasis is placed on categories, places, and social positions, rather than on individuals. This philosophy is more dominant in Europe and encourages the development of “upstream health promotion policies” rather than a “downstream curative focus” (McKinlay and Marceau 2000, pp. 26–27).

A risk of individualistic approaches to public health is the medicalization of the food supply, in which food is increasingly treated like a drug with specific properties for treating or preventing disease. Under such a scenario, illness becomes viewed as a matter of the individual making poor diet choices, ignoring the multifactorial personal and social circumstances that create or inhibit health. Lawrence and Germov are critical of this view, as it “represents a pathologised and reductionist approach to health promotion and food consumption” (1999, p. 60). McKinlay and

Marceau (2000) are gentler in their critique, celebrating the past achievements of the medical/individualist paradigm in tackling infectious and chronic diseases while calling for new approaches to the public health challenges of the twenty-first century. They emphasize that a holistic, collectivist public health model that distances the field from the dominant medical paradigm is necessary to address the ecological scope of current and future public health challenges, including global environmental degradation and widening social inequalities.

The Political Context: Deregulation

Historically, legislation in most countries has prohibited the use of product health claims that seek to link a food with the treatment or prevention of a particular illness (Heasman 2008). However, hand in hand with the creation of new, health-oriented products came the desire for food companies to market them for their health benefits. The result has been partial and inconsistent deregulation surrounding the use of health claims, which varies considerably from country to country (Hasler 2008; Katan 2004).

The current regulatory situation in the United States has its origins in the Nutrition Labeling and Education Act (NLEA) of 1990 and the Dietary Supplement Health and Education Act (DSHEA) of 1994. Under these groundbreaking acts, food manufacturers were for the first time permitted to make a limited number of specific health claims, including structure/function claims linking a product to a particular biological action, on food labels for marketing purposes. The Consumer Health Information and Better Nutrition Initiative of 2003 further reduced the level of scientific evidence required for companies to make health claims on product labels (Nestle 2002). Although the FDA distinguishes between levels of scientific evidence by allowing different types of health claims on product labels, studies have shown that consumers have trouble differentiating between qualified and unqualified health claims (ADA 2009).

The regulatory context in Europe has been equally contested and even more fragmented. Throughout the past few decades, many countries developed their own regulatory frameworks for the use of voluntary health claims on functional foods. However, in 2007 the European Union Regulation No. 1924/2006 was passed, enacting EU-wide regulation of health claims permitted for functional foods and establishing a set of criteria for the scientific substantiation of health claims (Asp and Bryngelsson 2008). Similar legislation has been approved in Australia and New Zealand as of late 2012. Both of these regulatory schemes seem to establish much more rigorous standards for the approval of health claims on functional food products than those of the United States; however, it is too early to assess their impact.

The challenge for all regulatory bodies charged with evaluating functional foods and health claims is that they are being asked to develop legislation in advance of a significant body of evidence supporting such regulatory change. The reason for this is that the investment in research and development required to develop functional food products is substantially higher than that of their conventional counterparts. Many stakeholders are open about the fact that if regulations are not relaxed, much research and development of functional food products is unlikely to proceed (Heasman 2008).

From an industry perspective, the motivation to produce functional foods is largely a factor of decreasing profit margins in processed food markets and economic pressures of shareholder imperatives. The current global food system is characterized by a highly competitive marketplace in which product differentiation is often elusive. Additionally, investor excitement over technologically oriented market sectors has led to decreased investment in the slow-growing food industry. As pressure to create a strong return on investment mounts, functional food science presents an opportunity for companies to produce value-added products that are truly innovative. In support of this approach is the widely held food industry conception of “a new consumer relationship with health, and this includes attitudes to food” (Heasman and Mellentin 2001, p. 19).

Factors leading food producers to adopt this view include an aging population increasingly susceptible to chronic disease, market research indicating increased consumer interest in personal preventative health measures, and the rising cost of healthcare.

Heasman and Mellentin (2001) characterize partial deregulation coupled with cautionary advice as a “wait-and-see approach” to functional foods public policy, which is “largely reactive and ... could exaggerate confusion in the public mind” (p. 76). Alternate policy approaches include resistance to industry demand combined with tough regulations allowing only strongly scientifically substantiated health claims, or active embracing of the functional foods concept and encouragement of ethical functional food development.

Criticisms of Functional Foods

As a public health measure, the use of functional foods has been criticized because it does not address the social – including economic, cultural, educational, and environmental – causes of poor health. Health is not simply a product of diet but also consists of a social dimension through which people express themselves and connect with others. Therefore, a healthy society not only has access to a variety of affordable, nutritious foods, but such foods must also be culturally relevant (Sibbel 2007). Further, any attempt to encourage the consumption of functional foods must take into account that the nutritional rationality competes with a host of other rationalities – including economic, social, and symbolic – in informing people’s daily food choices (Holm 2003).

Functional foods have also been criticized from the perspective of sustainability, in part because there is no effective way in which to measure their environmental impact. The World Health Organization has recognized that population-wide health interventions must be ecologically sound, as the sustainable preservation of environmental resources, including food, is a necessary condition for health (WHO 2009).

Therefore, one measure of the effectiveness of functional foods must be an evaluation of the resources they consume relative to the benefits they offer as compared to other types of public health measures. Although no infrastructure exists through which to measure the total environmental impact of functional foods, it is worth noting that such products are often highly processed, packaged, and widely distributed and may not reflect seasonality (Sibbel 2007).

Another aspect of a sustainable food system is that it is participatory in nature. Consumers must be able to participate in a feedback loop with producers as new scientific information emerges and new products are developed. Due to the highly technological nature of functional food products, the opportunity for consumer participation is limited and may even alienate consumers (Sibbel 2007). Studies have demonstrated a high level of consumer distrust and skepticism regarding foods with health claims (Sibbel 2007; Williams and Ghosh 2008).

Functional foods may send a confusing nutritional message to consumers by focusing on single nutrients, rather than the whole diet, for health outcomes (Holm 2003; Nestle 2002; Schroeder 2007; Sibbel 2007). Studies have shown that lay conceptions of healthy eating rely heavily on the concept of food groups or food pyramids (Holm 2003). Health claims of functional foods may encourage consumers to focus on specific products, single ingredients, and single outcomes, drawing attention away from food groups and holistic nutrition. Similarly, the blurring of traditional boundaries by functional foods that cross food groups – such as confectionary enhanced with calcium or soft drinks with added vitamins – may also distract consumers away from a food group orientation. Finally, “functional foods will introduce a detail oriented and fragmented way of communicating nutrition and healthy eating” (Holm 2003, p. 540). Such an approach may engender consumer confusion, distrust, and ambivalence, similar to the reaction to food safety concerns.

A further concern is that functional foods may not be accessible to those consumers who would be most likely to benefit from them. Consumer

studies have shown that functional food products are mostly preferred by well-educated women aged 30–50 – a population group who are among the least likely to need functional foods. Those who may benefit the most from functional foods include children, nonaffluent elderly, and consumers in the developing world. Yet these populations are not the target market of functional food manufacturers, as they are not in a financial situation to afford them (Schroeder 2007).

Perhaps most significantly, functional foods as a whole have not been sufficiently proven to be either safe or effective (Ernst 2001; Lawrence and Rayner 1998; Schroeder 2007). It is, in fact, impossible to assess the safety and efficacy of functional foods holistically, as each product or ingredient is designed to target specific biological functions in a specific population group. Therefore, the primary concern in assessing the safety and efficacy of functional foods is to ensure that sufficient mechanisms are in place to evaluate new products before they enter the market.

Support for Functional Foods and Future Prospects

Behind the functional foods concept is a genuine attempt to improve human health through advancements in nutritional science and biotechnology. A number of research organizations, such as the Functional Foods for Health Program at the University of Illinois, are dedicated to the identification and development of disease-preventing and health-promoting food components and products, as well as to raising the profile of functional foods. An example of the application of such research is the addition of folate, a nutrient hard to obtain in the average diet but important to fetal development, to cereals and other food products. However, the successful integration of truly functional foods requires proactive policy regarding their regulation. Such policy should ensure that those functional foods meeting strict regulatory criteria are widely available, affordable, accessible to those whom they benefit, and acceptable in

the minds of consumers (Heasman and Mellentin 2001).

Evidence regarding the impact of functional foods and health claims on public health is insufficient to recommend them on a large scale (Lawrence and Rayner 1998; Schroeder 2007). However, they may be useful in specific cases, for particular populations or individuals. In this sense it is useful to regard functional foods in the context in which they are developed – as part of an individualized, medicalized framework in which clinical trials conducted on individuals are the substantiating research methodology. As such, Lawrence and Rayner (1998) recommend a general prohibition on the use of health claims, with exemptions made on a case-by-case basis to allow food manufacturers to take advantage of emerging scientific data in order to develop products that may benefit certain individuals. Similarly, Katan and Roos (2004) advocate stricter regulations that prohibit the use of “soft claims” but allow the use of “hard claims” when there is sufficient agreement of scientific evidence. The intention of such recommendations is to prevent the widespread marketing of foods as medicines, but still enable innovative research and development.

Functional foods have been recognized as a growing market for food manufacturers. In order to substantiate health claims for innovative products, industry-funded research is likely to be biased toward investigating the bioactivity of single foods and their components. It is also likely that the industry will promote health education messages regarding the benefits of single foods. In order to counterbalance these efforts, publically funded research into the relationship between health and the diet as a whole is recommended, as well as increased educational efforts to encourage balanced and varied diets (Holm 2003).

Heasman and Mellentin contend that in order for the functional foods concept to be effective, it must “produce both healthy people and healthy profits” (2001, p. 263). As such they propose a new business model which they term the “healthful company.” Such a business is centered around the holistic health of the consumer, takes strong

ethical and social responsibility, builds genuine relationships with consumers, is both product and service oriented, and is knowledge rich. Under this model, they suggest that the need to rely on regulated health claims becomes incidental, as the company will demonstrate its claim through its actions. They point to the long-term success of the Japanese probiotic dairy company Yakult as an example of a successful “healthful company.”

Summary

The growth of functional foods over the past three decades is largely a result of an increasingly individualized view of public health, a political climate of market deregulation, and a focus on the role of individual nutrients, as opposed to the whole diet and other lifestyle factors, in health promotion and disease prevention. Though notoriously hard to define, functional foods are intimately tied to the ability of food manufacturing companies to make health claims about their products. Historically such claims have been prohibited in most countries, but increasing pressure from the food manufacturing industry has led to new legislation allowing some health claims. Such regulations, the types of claims they allow, the degree of scientific substantiation required, and their enforcement vary greatly from country to country.

In challenging conventional understandings of the role of the whole diet in nutrition and health, functional foods invite criticism from public health and nutrition scholars and officials. Further, the ethics of functional foods have been called into question from the perspectives of safety, efficacy, sustainability, and access. Recommendations for the future of functional foods call for tighter regulations and a higher level of scientific substantiation, as well as ethical business models focused on the holistic health of the consumer. Publically funded research initiatives to counterbalance the weight of industry studies are advised. However, with the influence and funding of the processed food industry behind them, functional foods marketed with health claims are likely to increase in prominence in the future.

Introduction

“Let’s face it,” says Marion Nestle, of the Department of Nutrition and Food Studies at New York University, “functional foods are about marketing, not health. Fruits and vegetables are already perfectly adequate to help prevent cancer and heart disease” (Brophy and Schardt 1999). Nestle’s statement points, perhaps unconsciously, to the entrenched thinking of many scholars and scientists of nutrition that food is more than just

nourishment and that it is an active agent in the body. More than simply “filling us up” or tasting good, the belief is that food contains “bioactive” compounds that are essential to health and well-being. Because nutrition policies encourage nations to pursue “health” through eating, food scientists, nutritionists, and biochemists continue their research into the function of particular nutrients in the body, the foods in which those active ingredients are located, and how best to isolate those compounds. It is this undertaking that grounds the emergence of “functional foods” as a consumer product category. The role of food as weapon for combating disease has prompted the category of “functional” food or beverage to be identified as one of the fastest growing market segments of the twenty-first century. Accordingly, food producers have seized on this trend to “functionalize” many processed, industrial food products like cereals, snack foods, and drinks through the addition of “magic bullet” ingredients believed to confer specific physiological benefits in the body. Cereals now lower cholesterol, yogurt improves brain function, and orange juice improves bone health. At the time of publication, the United States remains the largest market for functional foods; however, Asia-Pacific and developing nations are anticipated to be areas of tremendous future growth (Global Industry Analysts 2012). The purpose of this entry is to provide a brief historical context for the emergence of functional foods as a marketing category, identify the social and cultural conditions that have made functional foods possible, and outline the key industry players, political bodies, and policy measures that inform the marketing of functional foods.

Social and Cultural Conditions for Functionalized Food

Ancient, Classical, and Renaissance Legacies

“Let food be thy medicine and thy medicine, food” – *Hippocrates*

As the quote by Hippocrates indicates, civilizations have been functionalizing foods for

centuries (Medicinal Food). Lay knowledge and folk wisdom about what to eat to remedy illness, biliousness, or weakness circulated within traditional communities, as it continues to do today. Prescribing chicken soup for a cold is an example of a food whose perceived function is more of the product of history and culture than science and whose claims to make one healthier are neither officially tested nor regulated. Roman physician and surgeon Galen wrote treatises on humoral theory, food, and diet and included essays entitled “On Barley Soup” and three volumes of “On the Powers of Foods.” In “On Barley Soup” Galen touted its purgative abilities, its ability to reduce fevers, and its power to convert “semi-putrid juices into good ones” (Grant 2000). Galen held that medical treatment through diet depended largely on the individual’s humoral composition and that foods, while different than drugs, could be used medicinally. Some foods had “hot and harsh powers, such as garlic, leeks, and onions,” and others, like wine, were cooling, and too much would cause “a cold disease.” Much early food functionalization grouped foods by their capacities to heat and cool the body, and Traditional Chinese Medicine (TCM) and Ayurvedic medicine used yin and yang and doshas (body constitutions) to prescribe certain foods over others, prescribing the consumption of particular foods to alleviate particular health grievances in particular individuals or to promote ideal health in others. As such, early food functionalization was closely tied to culture, the healing arts, and religion. With the advent of the university, the professionalization of medicine and the rise of scientific research, the relationship between food and its effects on the eater, became more formalized.

Formalized Science and Functional Foods

Crucial to the emergence of the category of “functional food” was the rise of modern science and of the field of nutrition. As scholars began to investigate eating, food, and the body through the lens of formalized scientific knowledge, foods began

to be understood by their constitutive chemicals, rather than by their essential qualitative natures (i.e., hot or cold, yin or yang) (► “Functional Foods”). With increasingly microscopic and atomic technologies, scientists isolated compounds they thought acted in the body and produced data and analyses of a food’s composition. This shift began in the early modern period (ca. 1450–1750), during which time European intellectuals, inspired by classical Greek and Islamic mathematics and sciences, began to study nature as an objective, controllable entity. Early dietary studies were conducted to examine and establish the functions of foods even before scholars had identified the active, biological ingredients involved. The first example of an empirical approach to identifying specific food ingredients acting in the body was the studies of scurvy done in the 1600s and 1700s by English naval surgeons John Woodall and James Lind. In 1617 Woodall wrote “The Surgeon’s Mate,” in which he described the symptoms of scurvy and pointed to lemon juice as the cure. He then persuaded the East India Company to provide lemon juice to its sailors. In 1747, Lind conducted what is considered the first controlled experiment to establish the link between citrus fruits and a remedy for scurvy. He divided patients into six pairs, giving each group a different remedy. Only the ones receiving oranges and lemons recovered (Leger 2008). This discovery set a precedent for the scientific method being applied to identify the relationship between a particular food and the prevention of disease.

In the eighteenth century, Antoine Lavoisier’s research into animal metabolism and respiration, published as *Memoires sur la chaleur* in 1783, formalized the “calorie” as a unit of food and energy and begat a model of the body that processed food in a mechanical way, transforming food into energy. The application of the calorie to food was one of the earliest explicit and formal scientific assertions of a food’s function. Food became a measurable unit of fuel. Building on Lavoisier’s work on heat, metabolism, and calories, nineteenth-century German scientists Justus Liebig, Carl von Voit, and Max Rubner all worked to improve techniques of bomb and respiration

calorimetry and proximate analysis to better isolate the molecular components of foods. This catabolism of food into discrete units of energy, fat, carbohydrates, and proteins, and the study of how these components acted in the body provided the foundation for the creation of the science of “nutrition” (Rossiter 1975; Cravens 1996).

By the early twentieth century, formalized science had become the authoritative forum for understanding food from its production to its ingestion in the human body. Science functionalized food through the identification of certain nutrients that contributed to, or helped prevent, disease. Clinical trials and controlled experiments generated data about food and eaters to enable medical practitioners to treat food prescriptively. In the North American context, historians of science point to the late 1800s as the beginning of the era that advanced the rise of science in American public life. Alongside the application of science to the workplace, public infrastructure, and social life, the formalization of both nutrition science and home economics curricula fostered the application of the methods of science to food and eating. The US Department of Agriculture was created in 1862 with the goal to “becom[e] a great science-producing agency of government” (Cochrane 1993). The USDA funded and supported universities, nutrition scientists, and home economists as well as developed standards for food producers, food quality inspectors, food industries, and farmers. The agency principles and funding structure facilitated the epistemological assumption that “knowing” food meant knowing how it acted in the body. As such, it provided a new framework for categorizing food. Food meant proteins, carbohydrates, and fats, and the way a food was understood to function in the body stemmed from this categorization.

Wilbur Atwater modeled the body after the closed thermodynamic system of physics, and his experiments promoted a practical economics of the body as fuel in, energy out. Atwater ran dietary studies with different populations of people and wrote that “by comparing the results of many such investigations it is possible to learn about how much of each of the nutrients of

common foods is needed” (Atwater 1902). With the discovery of the water-soluble “vital amines” of B1, B2, B3, C, and D by Casimir Funk beginning in 1912 and fat-soluble vitamin A in 1913 by Elmer McCollum, food became functionalized in a new way. The discovery of vitamins showed that all calories, or even all fats, proteins, or carbohydrates, were not created equal. Vitamins and minerals introduced a qualitative measure for foods, and as the century saw more links between vitamins, minerals, and deficiency diseases, categorizing foods based on their function provided a more targeted way to avoid these diseases. By the mid-twentieth century, the prophylactic health benefits of many nutrients had been identified: Vitamin B1 combated beriberi; niacin, pellagra; vitamin D, rickets; vitamin A, night blindness; iron, anemia; and iodine, goiter.

This paradigm of academic scientific research was and remains a fundamental ontological linchpin in defining “good” food. Alongside laboratory research into the relationship between food and disease came dedicated research centers, government grants, more precise and specific research technologies, and journals and professional associations whose focus was on studying the link between food components and health. In 1928, the *Journal of Nutrition* was established alongside the American Society for Nutrition, and in 1941 the British Society for Nutrition. These publications and societies helped cement the professionalization of the field, and by extension, they created an academic and social space for functional foods to exist.

Concurrent with the rise of the formal sciences was the industrialization of food production and the concentration of ownership among food manufacturers. To address the changing demands of sellers in an industrialized marketplace, the formal discipline of “marketing” was born at the turn of the twentieth century. The self-conscious practice was first integrated into university curricula at the University of California, Berkeley, and the University of Illinois in the late nineteenth century, although the field was arguably the product of international collaboration between American and Continental scholars (Bartels 1988). The establishment of professional organizations in

food and nutrition therefore occurred contemporaneously with the establishment of professional marketing organizations such as the American Marketing Society (AMS) (precursor to the American Marketing Association (AMA)) in 1931. An era of modern food production and marketing was born.

The Rise of Food Marketing: Federal Food Guides and Advertising

Marketing is conducted not only by private corporations but also by different levels of government and a range of public and nongovernmental institutions. Governments market ideas using tools such as information campaigns, pamphlets, and guides in attempts to influence social behavior. As scientists at work in the field of nutrition arrived at more precise techniques for measuring foods and eaters, they were able to identify more elemental and molecular components of food. The isolation of active compounds in food created the space for a wider range of food components to become functioning agents in the body – not only macronutrients like carbohydrates and proteins but vitamins, minerals, and, more recently, fatty acids, amino acids, and phenols. National governments funded much of this research, and they set to publishing it in the form of food guides with the goal of improving public health. Thus, in the early part of the twentieth century, the formal food guide was born. Food guides reflected national government's attempt to educate the public to understand food as a vector for nutrients, whose function was to keep disease at bay. The first USDA food guide aimed at children and published in 1917 categorized food by its presumed biological function in the body. Milk was deemed particularly important. The USDA noted that although milk is a liquid, it contains, if the water were driven out of a quart, “half a cupful of the very best food substances, including butter fat, a kind of sugar not so sweet as granulated sugar known as “milk sugar,” and also materials which are needed to make muscles, bones, teeth, and other parts of the body” (Hunt 1917). The

goal of the food guide was to teach the public the proper way to eat, and while the notion of “proper” would change over time, the USDA was consistent in encouraging the consumption of certain foods over others (Nutritionism).

The first population-wide dietary guidelines came in 1917, encouraging Americans to select their meals based on a food's pragmatic value: fuel. While fuel was qualitatively judged, early on it remained the function of food. Cereals were considered good sources of fuel because they were inexpensive and preferred over fruits, vegetables, meats, and sugars, which were more expensive. In the 1920s the addition of iodide to salt served as one of the first functionalized food staples, as iodine had been identified to prevent goiter. Morton Salt advertisements warned of contracting goiter and that their iodized salt was recommended by “high health authorities” because iodide was “vital to the normal function of the health-governing thyroid in the neck” (► [“Company Identity in the Food Industry”](#)). In Britain and France, Nestle's “milk food” touted itself as “a perfect nutriment for infants, invalids, and children.” Kellogg's Pep cereal was one of the earliest actual foods that were promoted as encouraging a specific physiological function; advertisements from the 1920s describe Pep as containing bran, which was “mildly laxative.” Pep thus “helps stop constipation!” (Playtime Pep 1927).

In the period from the Great Depression to the rationing of World War II, the development of daily nutritional minimum requirements articulated by the League of Nations, the British Medical Association, and the US Department of Agriculture marked a shift in the functionalizing of food. As governments established nutrient minimums (recommended dietary allowances, or RDAs, were first established by the United States in 1941), food constituents became explicitly prophylactic to a degree they had never been before. Federally mandated minimum regulations for nutrient intake provided authority for the food industry to market its products as essential tools for maintaining the well-being of the nation. The manufacturer of Kix cereal, General Mills, advertised from the 1940s that it

“consulted leading nutrition authorities before making Corn Kix,” and as such, it contained vitamin B, vitamin D, calcium, and phosphorous cartoon character. Brer Rabbit claimed that Brer Rabbit Molasses was “rich in iron” in an ad from 1941, and the US government endorsed “Vitamin Donuts” that were each fortified with “a minimum of 25 units of vitamin B1.” Breakfast powders like Ovaltine, Horlicks (in the United Kingdom and Asia), and Milo (in Australia and Asia) were some of the first processed foods engineered specifically as vehicles for providing the body with the required daily vitamins and minerals.

These new fortified products did more than simply provide ingredients that had physiological benefits. Their secondary function was to reformulate the category of “food,” through marketing. Advertisements for Ovaltine show that the function of “tasting good” to the body became supplanted by “doing good” to the body. These milk supplements were not “foods” in the traditional sense; they were foods because they encouraged the eater to think about eating as an activity designed to fulfill the recommended allowances. An Ovaltine print advertisement from 1944 equated a bounty of food, its vitamin content, with two glasses of Ovaltine that were its nutritional equivalent. Ovaltine provided as much vitamin G (now known as vitamin B2 or riboflavin) as $\frac{3}{4}$ lb of sirloin steak, more niacin than five slices of fortified bread, more vitamin B1 than 3 servings of oatmeal, and more vitamin D than 10 oz of butter.

As the century progressed, concerns about the deficiency diseases that the RDAs were meant to address gave way to the new threat of chronic diseases like obesity, diabetes, and heart disease. The scientific lens through which to understand eating and the human body, however, remained. A postwar shift in regulatory and marketing efforts reflected unprecedented affluence in industrial nations and its associated chronic conditions. As a result, the 1980 Dietary Guidelines for Americans reflected a greater emphasis on nutrient intake (a shift echoed at the international level), recommending an avoidance of excess fat, cholesterol, salt, and sugar.

What Is in a Name? Marketing in the Age of “Functional Foods”

While the idea of eating according to a food’s function or in a healthfully prescriptive way has been around for centuries, the categorization of “functional foods” was formalized by Japan’s Ministry of Health, Labour and Welfare beginning in 1991 with the appellation “Foods for Specified Health Use” (FOSHU). The FOSHU designation was the result of a project developed in the mid-1980s by the Ministry of Education, Culture, Sports, Science and Technology that studied food’s role in the maintenance of good health or prevention of disease, beyond that of maintaining basic nutrition. Japan’s Ministry of Health, Labour and Welfare (MHLW) began regulating food label health claims as of 1991 under the Nutrition Improvement Law and Nutrition Improvement Law Enforcement Regulations (Fujimaki 1988; Arai et al. 2001).

In the United States, Canada, the United Kingdom, and Australia, there are no legal definitions of functional foods. Unofficial definitions of functional foods generally describe the foods as containing biologically active constituents that may or may not impart “physiological benefits and/or reduce the incidence of chronic diseases” (USDA, Health Canada, UK). The European Commission proposed in 2010 the following working definition for a “functional food”: a food that “beneficially affects one or more target functions in the body” (European Commission 2010). As academics, policymakers, and industry attempt to agree upon a definition, more legislations attempt to draw the distinction between functional foods and nutraceuticals, the latter of which are simply isolated products from foods that are sold as medicine. Functional foods are part of nutrition that professor of consumer behavior and nutritional science and former executive director of the USDA’s Center for Nutrition Policy and Promotion Brian Wansink calls “consequence-related” (Wansink 2007). According to Wansink, functional foods will act in the body beyond their simple “attribute level” of calories, fat, proteins, and carbohydrates. Functional foods may be in their natural, unprocessed

state – oats may be considered a functional food for its soluble fiber content that has been shown to reduce cholesterol – or they may be foods fortified to be functional through the addition of various nutrients. Fruit juices with added soluble fiber, granola bars with added probiotics, and peanut butter with omega-3 fatty acids are all cases of foods *becoming* “functional” through fortification. Omega-3 fatty acids do not naturally occur in peanut butter, and rolled oats and honey do not naturally contain probiotics.

In 1990, the US government passed the Nutrition Labeling and Education Act that required all packaged foods to be printed with a nutrition facts label (► [“Food and Health Policy”](#)). First introduced in October of 1989, this bill mandated that a rectangular information panel indicates the serving size and cholesterol, calorie, fat, sugar, protein, sodium, and carbohydrate content of the food in the package (► [“Food Labeling”](#)). The goal of this label was to “provide information regarding the nutritional value of . . . food that will assist consumers in maintaining healthy dietary practices” (NLEA 1990). The hope was that the nutrition facts label could act as a basis for the development of numeric standards to structure the food industry use of product health claims. The US Food and Drug Administration (FDA) has established regulations on the parameters for health claims associated with the specific, quantifiable chemical contents of a food. For example, the claim of “excellent source of” and “rich in” can only be applied to foods containing 20% or more of the recommended daily intake of the particular nutrient in each federally mandated “serving size.” The legislation makes no distinction between foods that have been artificially fortified and foods that contain the nutrient in their unaltered state. As such, both broccoli and artificially flavored and colored yogurt-covered fruit bites fortified with vitamins can be marketed as “a good source of calcium” and an “excellent source of vitamin C.” In the United States, having a particular nutrient is one way a food can be marketed, but lacking a particular nutrient is another. The FDA mandates that food can be marketed as “light” or “lite,” meaning that the package contains “a nutritionally altered product that contained one-third fewer

calories or half the fat of the reference food. If the food derives 50 percent or more of its calories from fat, the reduction must be 50 percent of the fat” (Stehlin 1993).

Presently, public and private “functional foods” research centers and units specializing in the isolation of the active biological components of foods can be found in Europe, Asia, Australia, and the Americas. Among the larger centers are the US Department of Agriculture (USDA)’s Functional Foods Research Unit, the University of Manitoba’s Richardson Centre for Functional Foods and Nutraceuticals, the New Zealand Institute for Plant and Food Research, and the Functional Food Centre at Oxford Brookes University. In 2008, the International Society for Nutraceuticals and Functional Foods met for the first time and founded the *Journal of Functional Foods*. As techniques become more specialized and scientists are able to isolate compounds with physiological benefits, the trend of fortifying foods with active ingredients that are not inherent will likely continue alongside robust advertising campaigns that tout a food’s active ingredient. While federal regulations rule what kind of health claims can be made and published on food packaging, it is often the case that magazines, television health shows, celebrities, doctors, and private industry equivocate when discussing certain foods they deem to be functional. Claims made by celebrities or media may have just as much impact as federal regulations in associating a food with a functional benefit in the public imagination. The surety with which celebrity surgeon Dr. Mehmet Oz has in stating that “broccoli is simply the best medicine we have (► [“Eating and Nutrition”](#)). It gets toxins out of your liver like no other medicine or food on the planet” (Health 2013) does harken back to Hippocrates’ quote. And while whole foods like green tea, broccoli, red wine, or almonds may be peddled as magic bullets for heart disease, hypertension, stress reduction, or cancer prevention, grocery store aisles are also filled with items like vitamin- and antioxidant-filled waters; fruit drinks with added omega-3 fatty acids; chocolate syrups fortified with vitamins B, C, D, and E, calcium, and iron; and even pet foods with added docosahexaenoic (DHA) acid for animal brain function.

Summary

Functional foods are likely here to stay. The wealth of research linking diet to health and the imperative for food producers to deliver novelty and added value suggest that this is one concept with enormous marketing potential. From the earliest recorded controlled experiments linking citrus fruit to a remedy for scurvy through the repackaging of infant nourishment into mix-and-stir proprietary formulas to the recent boom in novel “uppers” like caffeine- and herbal-infused beverages, the science of well-being has had powerful institutional investors (military, government, private corporations). Swiss-based Nestlé, the largest processed food producer in the world, has recently declared its intention to invest \$500 million in a new “Nestlé Health Science” division. In response to the question of why the company would invest in the nutrition business, president and CEO Luis Cantarell declared Nestlé’s mission to deliver good nutrition, health, and wellness – not just food. In 2010, Cantarell explained to *The Globe and Mail*: “We believe there is a convergence between food and pharma. . . Our food and nutrition expertise can help create a new industry [where] nutrition plays a bigger role in helping people who live with difficult chronic medical conditions” (Blackwell 2011; Melnick 2010).

The notion that food functions in the body to promote or thwart health – the very basis for the field of nutrition – provides functional foods with both their compelling rationale and their potential for abuse by marketers. As food manufacturers leverage tremendous resources to finance or leverage research into the action of food constituents in the body, consumer literacy in the complexities of human metabolism does not necessarily keep pace. Nor do the nuances of ongoing scientific research necessarily filter through into the sound bites of Dr. Oz or the health claims made on labels of fortified yogurts, chocolate syrups, and dog foods. As the recent health controversy in the United States over deaths linked to Monster Energy Drinks attests, the marketing of functional foods is an important issue for public concern (► “Functional Foods”). Food industry observers project future functional foods market valuations

into the hundreds of billions of dollars, annually. It may be that “functional foods” represent a sea change in food marketing – and, thus, of food consumption – a shift complicated by the term’s lack of definitional certainty and uneven international regulation. It appears certain, at least, that scientific research and commercial investment into the functional nature of foods will continue into the foreseeable future.

Fungi Ethics

Yogi Hale Hendlin
Department of Medicine, University of California,
San Francisco, San Francisco, CA, USA

Synonyms

Food as medicine; Mushrooms; Plant ethics; Soil ethics

Introduction

The fungi industry is mushrooming. Both in terms of an ever-increasing proportion of human diets and as a blight decimating crops as climates change and ecologies erode, fungi are an ever-present but oft-overlooked element of food and agricultural ethics. Perhaps because of fungi's Janus role as Paracelsian poison and medicine, depending upon the species, their discussion in food and agricultural ethics is only now emerging. Fungi ethics as a topic, however, cannot be broached without also implicating plant and soil ethics. Food nutrition and productivity reflect soil health, and attending to soil quality often requires reversing industrial agricultural practices to reconsider and relearn ethnobotanical practices such as *terra preta*, no-till farming, silviculture, and permaculture. The emerging ecological paradigm in forestry and agriculture increasingly attends to mycorrhizae, the undersoil fungal networks symbiotically transferring and breaking down nutrients between soil and plants. The presence or absence of healthy nutrient-transferring mycorrhiza has a tremendous impact on agricultural productivity and on soil fecundity.

In plant ethics, wanton destruction of plant life is legally discouraged in places like Switzerland, and the ethics of destruction of plant life must be balanced against the instrumental reasons that would cause this (Koechlin 2009). Fungi ethics, however, has yet to earn the respect it deserves in food and agricultural ethics. This entry explores how fungi are indispensable to agricultural and food ethics, and that the very field of agricultural and food ethics is reliant on the hidden yet pervasive labor of fungi.

Dimensions of Fungi Ethics

Fungi are in many ways an afterthought in standard accounts of ecosystems and agriculture. Common discourse places animals and plants as isolated organisms living in background habitats. But pervasive interactions between fungi and other kingdoms suggest reconsidering the role of fungi in agricultural and silvicultural habitats.

One of the leaders in research on mushrooms is Paul Stamets (2005), who, like Michael Pollan's enlivening of plants in *The Botany of Desire*, characteristically understands the mutuality of his experiences with fungi ("I have engaged fungi, or perhaps they have engaged me," x), by emphasizing that "the planet's health actually depends on our respect for fungi" (x). This respect for fungi opens into a broader term of engagement that presupposes right relationship with them. Thus, even as our primary relationship with fungi is one of productivity – e.g., using them for food, forest trees benefiting from mycelial networks to exchange nutrients and ecological information which facilitate their health – such processes are more than merely instrumental. In understanding the key interspecies role fungi play in all agricultural processes, this relationship can grow into respect. Stamets (2005) regards fungi as "keystone species" for their ability to "recycle" nutrients and restore dead matter back into (re)productive life.

Building on the plant intelligence work promulgated by Anthony Trewavas (2014) and others who have conceptualized the behaviors and chemical processes of plants as a plural sort of intelligence, indicating some sort of moral respect is warranted, so too do fungi exhibit other sorts of intelligence that justifies reconsidering respect for them (Tero et al. 2010).

Fungi and Soil Fecundity

With regard to both soil microbes and fungi, we can imagine "animal husbandry or gardening on a microscopic scale. By cultivating beneficial soil microorganisms on farms and in gardens, we can ward off pests and boost harvests" (Montgomery and Biklé 2016, p. 3). Arbuscular mycorrhizal fungi have existed as long as terrestrial plants have, and may have been necessary for plants to transition from water- to land-dwelling.

Mycelial Networks

Botanist Susan Simard has pioneered the study of the role of mycelial networks in forest ecologies.

Simard and her team have found through isotopic labeling that mycorrhizae in the soil arbitrate nutrient exchange between plants and trees in the forest (Selosse et al. 2006; Simard and Durall 2004). This interspecies collaboration involves subsoil fungal networks trafficking nutrients from dying trees to living trees, for example, and receiving nutrients as the broker for such symbiotic exchanges. These symbiotic exchanges suggest that the megafloora of sylvan and silvicultural ecosystems are in relationships of interdependence facilitated through subsoil mycelial networks. Paul Stamets, one of the popularizers of fungi ethics, understands mycelial networks as intelligent systems.

Endophytic Mycelia

As far as botanists can tell, all plants are infused by fungi, in the leaves, stems, trunks, roots, and crowns (Milius 2006). These fungal endophytes are not separate from the plant, as the plant and fungal structures are co-constitutive, much in the way that human cells and the human microbiome together form the human (Benezra et al. 2012). Indeed, fungi perfuse plants to such a degree that plant geneticists have long been flummoxed when plant assays produced DNA looking nothing like the expected DNA of the plant evaluated. It was only after repeated cases of "contaminated" plant samples did biologists finally realize that the fungus DNA they were instead receiving from their analyses were not exogenous to the plant but belonged to an endogenous other organism suffusing the plant in question (Camacho et al. 1997).

Fungi and Farming

The profusion of fungi species is second only to that of insects as a phylum, constituting 1.5 million distinct species. While most of these species are inedible or even dangerous, fungi in their various manifestations are an element of the agricultural landscape that cannot be overlooked.

Fungi can be either a blessing or bane to crops, depending on which fungi are present. While

mycorrhiza in the soil and healthy mutualist fungi are omnipresent in productive organic agriculture, rusts and mildews can destroy entire crops. The increased use of fungicides has often been seen in agricultural ethics as treating the symptoms with unintended consequences, rather than getting to the root cause (dampness, etc.). The problem with one-size-fits-all approaches to fungi that harm agriculture is that they often inadvertently undermine the beneficial fungi that plants need, beneficial fungi that in some cases act preventatively and guard against unwanted fungal infections.

From a resourcist perspective, fungi exist in the interstices between plant productivity, plant health, vegetation blight, and soil fertility. Stamets (2005) experiments show that plants with mycorrhiza in the soil produce more vegetation versus plants where mycorrhiza is absent from the soil.

The decompositional role fungi play in maintaining healthy ecosystems has often gone overlooked. Yet, natively processing matter through cultivating a healthy, diverse, mycological sphere is essential to resilient no-input ecosystems.

Biotrophic fungi only live on living plant matter. Powdery mildew and rust fungi, on the other hand, feed via structures extending from their hyphae called *haustoria* that penetrate the host plant's plasma membrane and absorb nutrients from the living plant in a fungi-plant hybrid. Necrotrophic fungi are parasitic on plants and disintegrate the plant cells they feed from, releasing nutrients but causing the plant's death in the process (Walters 2011).

Mushrooms are often used in bioremediation. Environments that have microbial pathogens, nuclear toxicity, or chemical effluent produce serious long-term health threats unless treated. Remediating landscapes via mycelial mats can occupy a central place in conservation ecology. Initial proof-of-concept experiments have successfully demonstrated the efficacy of fungi in bioremediation (Taylor et al. 2015).

Part of the 2013 FAO report proclaiming the need for agricultural worldwide to transition towards local organic farming (UNCTAD 2013), urging renewed attention on soil, is intimately related with realizing the importance of fungal

mycorrhiza in maintaining soil fecundity, the non-negotiable source of nutrients for food grown (Badgley et al. 2007).

Humans are not the only animal that farms fungi. Leaf-cutter ants excavate underground caverns as large as a human's living room to cultivate fungi to break down the cell walls of the leaves they harvest to make them consumable (Hölldobler and Wilson 2010).

Eating Mushrooms

Ethically, eating mushrooms constitutes – in the best case – a harmless form of satisfying human needs. Many meat replacement products use mushrooms to create the *umami* taste and consistency desired. Insofar as only the fruiting body of the fungus is plucked, the mycelial mat keeps on producing mushrooms and is capable of reproducing for many seasons, as long as the organism still has substrate to decompose and metabolize. Thus, eating mushrooms, in sustainable amounts, at least, perhaps is one of the most ethical of foods.

Fungi, of course, are primarily known popularly through their delicious and nutritious fruiting bodies, the mushrooms purchased at farmers' markets and grocers. Mushrooms come in a dizzying array of varieties, some with medicinal properties, other with hard-to-find nutrients and minerals, others with high protein content, and, of course, others psychedelic or poisonous. The UK company Quorn since the 1980s has successfully converted conventional meat eaters to their mushroom-based (*Fusarium venenatum*) protein-rich product which delivers a satisfying *umami* texture and flavor, replacing and placating cravings for animal products.

Furthermore, some species of edible fungi only grow wild and cannot be cultivated. The prized matsutake (*Tricholoma matsutake*), which can fetch upward of one thousand dollars per kilogram for highest quality specimens, is one such species. The implications for foods, which cannot be controlled through agriculture or artificial means of cultivation, are those silvicultural virtues of attentiveness to the long-term health of the surrounding

ecology, and call for a localist mycological orientation.

While most mushrooms grow out of the soil or are parasitic or symbiotic with trees, the medicinal mushroom *Cordyceps* invades ants, turning them into fungi-controlled zombies where the fungus forces an infected ant to climb up to a high leaf, chomp down on it with its mandibles, and die. This enables the *Cordyceps* spores to rain down on ants below on the forest floor, infecting other ants (Evans and Samson 1982).

Mushrooms as Medicine

Since before humans engaged in agriculture, fungi have played a pervasive role in human lives, including analgesic, antiseptic, fire tinder, spiritual, and myriad other uses (Bortenschlager and Oegg 2012). Oyster mushrooms produce the cholesterol-lowering molecules active in the drug lovastatin, and maitake mushrooms (*Grifola frondosa*) have been shown to help reduce breast cancers (Zhang et al. 2017). In Chinese medicine, reishi, chaga, lion's mane, conks, turkey tail, and many other mushroom varieties have almost a sacred status in the pantheon of healing medicines for their power as tonics and to heal specific ailments. Western science has validated medical ethnobotanical finding that the ergosterol peroxide found in chaga (*Inonotus obliquus*), for example, exhibits anticancer properties (Kang et al. 2015). The medical and pharmacological applications for fungi are still in their infancy.

Penicillin and many other antibiotics are derived from fungi and then isolated. In response to penicillin- and antibiotic-resistant bacteria, going back to the fungal source of antibiotics might provide succor against bacteria resistant to lab-cloned antibiotics (He et al. 2016).

Industrial and pharmaceutical capture of traditional medical ethnobotanical fungi, as in other cases, poses significant potential risks. Lack of compensation to the indigenous peoples who figured out the medicine's curative properties, patenting of specific varieties of wild species, and the lionizing of syntheses and extracts of

particular compounds while denigrating or even banning use of the whole plant or fungi are all actions with precedent that would violate ethical reception of medicinal fungi into western science and medicine. Also lost in such reductionism are the potential entourage effects of so-called active compounds with other compounds in the whole fungi, which might potentiate the healing properties of the organism.

Conclusion

The culinary and agricultural role of fungi, while well-explored in some non-western contexts, is only recently gaining visibility in the west. Preventative fungi-infused agriculture can fill ecological niches in agriculture that would otherwise be prey to molds and fungal blights. Fungiculture for food, crop productivity, and bioremediation in industrially degraded ecologies promises alternatives to meat, artificial fertilizers and pesticides, and expensive and delayed conservation ecology strategies. Because of their inherently interspecies connections and ability to transmute minerals and nullify toxins as a first stage in succession, fungi ethics is a burgeoning field interspersed with plant ethics.

Gender and Dieting

Emily J. H. Contois
American Studies, Brown University, Providence,
RI, USA

[Gender and eating](#); [Gender and food](#); [Men and eating](#); [Weight loss](#); [Women and eating](#)

Introduction

Conventionally, the domestic sphere has been defined as a woman's world, thus feminizing food, shopping, cooking, and eating, along with nutrition, dieting, weight loss, and health. In contrast, men have occupied the opposing side of the nature/culture, private/public, domestic/commercial divide, typically eschewing food and the body as feminine focuses rather than masculine pursuits. As a result, much research has focused on women and dieting, but studies of the intersections between men, masculinity, and food are relatively limited. Work exploring men and dieting is particularly scant.

Sex difference discourse abounds in the study of gender and dieting, as the similarities and differences between what, how, and why men and women eat (and do not eat) speak volumes about how societies construct gender. Past research, which is summarized in this entry, has sought to define masculine and feminine foods, identify gendered food preferences, and chronicle how men and women each eat. To a degree, however, these efforts operate using a stagnant definition of gender. Feminist scholarship informs the discussion of gender and dieting, reinforcing the changing, variable, relational, and social meaning of gender and how it is performed in everyday life, such as through eating and dieting.

After defining dieting, this entry discusses philosophical approaches that influence its study. The entry next provides a history of modern dieting, using the United States as an example. The entry then summarizes what motivates individuals to "go on a diet" and the gender-specific characteristics of eating and dieting, generally in a modern Western context. Dieting is also discussed in relation to obesity, particularly in the United States where rates are relatively high and virtually equal among men and women.

Defining Dieting

Though also a noun and an adjective, the act of dieting is generally defined as eating sparingly and according to prescribed rules in an effort to

control weight. Dietitians and health professionals promote a "healthy diet," defining the term "diet" as the grand sum of all that an individual consumes. Weight loss diets on the other hand come in many packages. Some diets limit particular macronutrients, such as low-fat or low-carbohydrate diets. Some diets are developed and recommended by physicians, such as the Ornish diet, an extremely low-fat diet that researchers confirmed can not only treat but also reverse heart disease. Others are "fad" or "crash" diets, endorsing dietary changes that range from the extreme to the bizarre with potential effects ranging from disappointing to dangerous.

Individuals typically "go on a diet" to lose weight, often desiring to lose weight quickly, despite the generally accepted advice to lose no more than 2 lb per week. Health professionals nearly universally recommend a measured "lifestyle" approach, encouraging gradual weight loss by means of long-term behavior changes, such as reducing the amount of sugar-sweetened beverages one consumes or exercising for 30 min or more each day, rather than resorting to crash diets, which typically do not result in lasting weight loss. The cycle of weight loss and gain is referred to as "yo-yo" dieting and may have detrimental health effects, including emotional and psychological distress.

Furthermore, dieting is considered by many to be a gateway of sorts to eating disorders. In some individuals, constant anxiety regarding food, eating, and weight can cluster as disordered eating practices and even transform into full-blown eating disorders, such as anorexia nervosa, bulimia nervosa, and binge eating. For this reason, the high rates of dieting among women, particularly young women and girls, can be concerning. Notably, 90–95% of those with eating disorders are female, though recent studies reveal that these widely accepted statistics might underestimate the male burden of eating disorders (Strother et al. 2012). For example, young men use anabolic steroids at approximately the same rate that young women develop anorexia or bulimia. In general, eating disorders among men are characterized as "underdiagnosed, undertreated, and misunderstood."

Philosophical Approaches to Dieting

As discussed by the contributors to *The Atkins Diet and Philosophy* (Heldke et al. 2005), a variety of philosophical approaches inform a study of dieting. While most major Western philosophers do not offer recommendations for a healthy lifestyle, Nietzsche argued that the human body and mind find their ability to function optimally – and to become and produce art – when properly fueled by a balanced diet, personalized to the individual (Irwin 2005 in Heldke et al. 2005). Notably, Nietzsche concerned himself with not only good nutrition at the individual level but also balanced eating as a form of cultural nutriment as well (Bamford 2005 in Heldke et al. 2005). In addition, Dewey, Hume, and Aristotle each endorsed forming strong habits under unimpassioned circumstances (Auxier 2005 in Heldke et al. 2005). Thus the habits of “healthy” eating created and practiced in the absence of desire will prevail when tempted, perhaps by sweet or fattening foods. Dennis (2005 in Heldke et al. 2005) applies Kant’s ideas on individual decision making (autonomous, unfree, and random) to personal eating habits and food choices, revealing yet another of the many ways that philosophers have approached the topics of eating and dieting.

US History of Dieting

Beyond philosophical approaches, historical context also shapes dieting practices. While dieting histories differ across the globe, Hillel Schwartz’s *Never Satisfied: A Cultural History of Diets, Fantasies and Fat* (1986) is one work that chronicles the history of dieting in the United States. As he describes the slimming methods of successive time periods, Schwartz argues that dieting and the desire to control fatness are woven into the cultural fabric of the United States, representing people’s confused postindustrial desires, embodied in the contradictions of abundance and restraint, affluence and piety.

Notably, while contemporary societies conventionally view dieting as the preoccupation of women, dieters and diet authors prior to the

twentieth century were more often men, defeating gluttony through masculine rationality. Schwartz begins his history with the first American dieters, who followed the advice of health reformer Sylvester Graham, who with biblical zeal encouraged a simple and wholesome diet, emphasizing whole-wheat bread. From these origins, Schwartz traces social perceptions of body weight, which have evolved to view obesity as a threat to physical and moral health, vilifying fat as it has become further medicalized.

Schwartz’s work reveals the somewhat chaotic and nonsensical history of diet regimens and the political, economic, social, and cultural factors that influence their rise and fall. Diets mirror society itself at a particular historical moment. Dieting practices also reflect a society’s perceptions of gender and gender-specific characteristics, particularly ideal bodies.

Reasons for Dieting

Going on a diet often involves restricting or even “giving up” foods that one enjoys eating. Given that dieting can be an unpleasant experience physically, emotionally, and psychologically, why do individuals voluntarily diet? Independent of gender, the greatest motivating factor for going on a diet, or changing eating behavior, is to improve one’s appearance, particularly in order to become more attractive to an existing mate or future romantic partners (Kiefer et al. 2005; Boyes et al. 2007). Body dissatisfaction is generally what fuels weight loss efforts, as, in many cases, one aspires to a gender-specific physical ideal.

In many Western societies, pressure to conform to a thin, ideal body weight inundates women, particularly through mass media. Notably, more women than men are dissatisfied with their bodies (De Souza and Ciclitira 2005). Particularly since the 1960s, women have aspired to a thin ideal, a culturally constructed and socially encouraged form of physical perfection (Bordo 1993). These conflicted efforts intersect with the construct of weight as a quantity under individual control, resulting in a personal responsibility to manage, limit, and restrain the body. In this way, weight in

excess of the ideal is experienced as a failure and source of shame. Employing the term normative discontent, Rodin et al. (1984) argue that society not only propagates body ideals but also normatively accepts women's discontent with their bodies when they do not meet these ideals, which are out of reach for most individuals.

While focusing on female eating, dieting, and bodies in her work, *Unbearable Weight* (1993), Susan Bordo evaluates men in *The Male Body* (1999), revealing increasing male body anxiety. Just as for women, men are held up to an equally unrealistic ideal of the lean, chiseled, and highly muscular form. Along with an increasing focus on muscular bodies, analyses of popular culture have found an increase over the past 30 years in the number of images featuring semi-naked men. In part because of this media coverage, men also experience body image concerns, which appear to have begun increasing in the latter half of the twentieth century. For example, a recurring *Psychology Today* survey documented significantly increasing male body dissatisfaction over the course of 30 years with 15% of men experiencing body dissatisfaction in 1972 compared to 34% in 1985 and 43% in 1997 (Garner 1997). Furthermore, among college-aged study subjects, men and women have been found to experience similar body dissatisfaction; for example, 95% of men in one survey were dissatisfied with some aspect of their bodies (Mishkind et al. 1986). These burgeoning concerns have drawn scholarly attention, yielding new concepts, terms, and areas of study, which explore men and their relationship to their bodies, such as the Adonis Complex and muscle dysmorphia.

Gender and Eating

While men and women may experience similar body dissatisfaction, current research demonstrates several gender-specific differences in what and how they eat. From the beginning, men and women differ physiologically in their dietary needs. For example, men typically contain more lean body mass than women and thus possess a higher metabolic rate and require a higher energy

intake. On the other hand, women may experience physiological processes that men do not, such as menstruation, pregnancy, and breastfeeding, which alter a woman's eating habits and dietary needs. Furthermore, men and women's bodies differ. To provide a single example, to meet the demands of reproduction, women's bodies contain more body fat than men. Standards recommend that women's bodies contain 20–30% fat, compared to men's recommended 10–20%.

Beyond physiological determinants, men and women differ in other marked ways. In their review of gender and eating, Kiefer et al. (2005) summarize social perceptions of gender-specific differences that are related to nutrition. For example, the authors summarize a general dichotomy in nutritional behavior, stating that men are perceived to eat large portions quickly, while women exercise moderation and restraint. It is considered masculine to eat with gusto, while women are expected to demonstrate their femininity as light and dainty eaters. These social perceptions are exemplified in food marketing. For example, Hungry-Man dinners, microwavable meals available in the United States and generally composed of meat and starch combinations, are overtly named, identifying the product with brawny masculinity. Some dinner packages are stamped with the phrase "1 pound of food," emphasizing the large, heavy, manly quantity of food. Conversely, Dannon Light and Fit[®] yogurt sells low-fat dairy products with feminine flair. With the words light and fit, this brand describes not only the yogurt but also the body characteristics that the female consumer desires to acquire through consumption habits. The purple packaging and feminine fonts confirms that yogurt is not only a food that both men and women generally consider feminine but also a product uniquely formulated for female customers.

Kiefer et al. (2005) also discuss additional social perceptions of diet and gender. When categorizing food preparation skills, men are associated with barbecuing and grilling while women with cooking and baking. Specific taste preferences are even gender mapped, equating masculinity with savory and bitter flavors and femininity with mild, sweet, and light ones. The authors also

summarize how men and women differ in their approach to food. From adolescence, women are more interested and more knowledgeable on nutrition topics, more likely to control their body weight, at higher risk for eating disorders, and more likely to seek out nutrition advice than men. Conversely, men experience fewer food problems but tend to be more overweight. Men typically carry more weight in the abdominal region, which tends to be visceral body fat and associated with a higher risk of disease. While men are less likely to practice health-promoting behaviors and have higher risk for certain diseases, women experience eating behavior problems more often than men. In addition, women were found more likely to eat in stressful situations and to experience strong cravings for specific sweet foods.

The composition of men and women's diets also tends to differ. Typically, men's diets include more meat, animal products, alcohol, and high-starch foods, such as potatoes and bread, while women's diets include more fruits and vegetables, cereals, and dairy products (Kiefer et al. 2005; Jensen and Holm 1999). While women snack more often than men, both men and women show preference for sweet foods, such as chocolate, ice cream, cake, and cookies; women consider sweets to be less healthy but enjoy them more than men (Kiefer et al. 2005).

Dieting Differences Between Men and Women

Just as there are differences in how men and women eat, there are also differences in how they diet. The gender-coded nature of food production, acquisition, preparation, and consumption links women to food, both materially and ideologically. Furthermore, women have historically been more likely to diet and attempt to lose weight because of social attitudes regarding women's bodies, particularly Western ideals that privilege thinness. In addition, the historically feminine roots of nutrition science may explain men's comparative lack of interest in food, nutrition, and health. Men typically approach food

with an uncomplicated and enjoyable attitude, while women often have a more ambivalent and complicated relationship with food. Independent of actual body mass index (BMI), women are less satisfied with their bodies than men and more often aspire to the beauty ideal (Kiefer et al. 2005).

In a qualitative study of six British men's attitudes regarding dieting (De Souza and Ciclitira 2005), male participants stated that men and women diet for different reasons, acknowledging the increased pressure women are under to be thin but also discussing the different pressure experienced by gay men. While heterosexual men have, until relatively recently, experienced a lesser pressure to conform to a lean, muscular ideal, such a physical form has been longer embraced in the gay community. Such physical preferences result in higher rates of dieting and increased acceptance of dieting in the gay community compared to heterosexual men, as well as higher rates of eating disorders, such as body dysmorphic disorder and muscle dysmorphia (Strother et al. 2012).

Among young people, women typically desire to lose weight, while young men aspire to gain weight (Page and Fox 1998), a trend that also holds true for older adults (De Souza and Ciclitira 2005). A 2006 study of Midwestern college students found gender differences in dieting practices, as well as eating habits and nutrition beliefs (Davy et al. 2006). Notably, a significantly larger percentage of women had tried diets, such as Weight Watchers (6.6% women vs. 1.0% men), low-fat diets (19.3% vs. 7.6%), low-carbohydrate diets (15.5% vs. 6.7%), and vegetarian diets (4.4% vs. 0%). In addition, more men reported having never gone on a diet (79.1% vs. 65.6%). Some posit that when men do diet, they are often more successful in their attempts than women because they have not dieted multiple times throughout life, which appears to be a health protective act.

Masculinity, Eating, and Dieting

Gendered expectations may play a role in the differences between how men and women eat

and diet. It is argued that hegemonic masculinity shapes male role expectations, which may affect men's views and actions with regard to health, eating, exercise, and weight management (Gough 2007). These hegemonic constructions of male behavior favor strength, independence, and risk-taking, in effect disqualifying the masculinity of health-promoting behaviors, such as eating fruits and vegetables. Eating without anxiety for weight gain or health effects (generally, eating in a health-defeating way) is also considered masculine, while concern for health and practicing healthy behaviors is perceived as feminine. Characteristics, such as ample portions, and specific foods, such as red meat, are routinely framed as masculine. Meat in particular is broadly associated across many cultures with qualities such as strength, power, and virility and is thus considered a quintessentially masculine food that also serves as a symbol of masculinity (Jensen and Holm 1999).

In her analysis, Bentley (2005 in Heldke et al. 2005) discusses how low-carbohydrate diets, such as the Atkins and South Beach diets, prominently include and promote red meat as a “diet” food, thus masculinizing the act of dieting. Unlike low-fat diets, which promote foods generally considered feminine – such as fruits and vegetables, whole grains, and reduced-fat dairy products – low-carbohydrate diets endorse foods considered manly in American culture, including meat and eggs. In the same way, however, Atkins also made it more socially acceptable for women to eat meat, especially in public places. Bentley also notes, however, that while the high cost of protein-rich foods typically makes low-carbohydrate eating a diet of the financially comfortable, low-carbohydrate diets also include a variety of lower class foods, such as pork rinds, revealing yet another dimension of low-carbohydrate diets.

The once extremely popular Atkins diet provides one example of men forging into the world of dieting without inhibition. Unlike women who nearly universally diet to lose weight, however, equal numbers of men aspire to lose weight as those who seek to gain weight in order to become more muscular (De Souza and Ciclitira 2005). Furthermore, men are more likely to manage weight by exercising rather than dieting.

The topic of men and dieting is an area worthy of further research. In their introduction to a special 2005 issue of *Food and Foodways*, Alice Julier and Laura Lindenfeld discuss the dually burgeoning fields of food studies and masculinity studies, identifying the many opportunities for these disciplines to speak to one another (Julier and Lindenfeld 2005). The articles featured in this special issue provide a robust overview and jumping-off point for such pursuits, though the editors acknowledge that the articles focus on affluent nations and socioeconomic backgrounds. While additional research in food and masculinity is encouraged generally, the editors specifically promote further studies of men and food “in ways that centralize race, nationality, migration, class, and sexuality in a global capitalist system.”

Gender and Obesity

In the United States and much of the world, obesity is a leading health concern. In 2009–2010, obesity prevalence for men (35.5%) and women (35.8%) in the United States was virtually equal (Ogden et al. 2012). What is concerning to some, however, is that while the obesity prevalence among women remained relatively constant over the course of a 10-year period, men's obesity increased from 27.5% in 1999–2000 to 35.5% in 2009–2010 (Ogden et al. 2012). It is within this context that discussions of gender and dieting occur. While the perceptions, ideals, eating behaviors, and dieting practices of men and women differ, current weight statuses, at least in the United States, are quite similar.

As a problem of excess body fat, the solution to obesity is often framed within the context of weight loss by means of reducing the amount of energy consumed and increasing the amount of energy expended. Dieting, whether following the guidance of a physician or adhering to the latest “fad diet,” is a popular method for weight loss. While data demonstrates that successful weight loss is difficult and rare, significant numbers of Americans are trying to lose weight. Of those at “normal” weight, 10% of men and 29% of women are dieting, compared to those who are overweight

(36% of men, 60% of women) and obese (63% of men, 70% of women) (Bish et al. 2005).

However these efforts are pursued, gender remains a powerful factor in dieting and eating behavior that is worthy of additional study, particular among men.

Summary

Dieting is generally defined as eating sparingly and according to prescribed rules in an effort to control weight. Just as men and women differ in their dietary needs and eating behaviors, they diverge in their approaches to weight loss. Both men and women are motivated by the desire to align their physical selves with culturally constructed body ideals, most often to appear more attractive. Dieting, however, is generally feminized. Furthermore, weight loss is the customary recommendation for combating obesity, rates of which are very similar among both men and women in the United States. In general, more research is needed in the area of men and dieting, a topic located at a unique juncture between food studies and gender studies.

Introduction

Chronic hunger and malnutrition are pervasive issues for large populations across the globe. At last calculation, the Food and Agriculture Organization of the United Nations estimated that

842 million people are not able to meet their daily dietary needs, the vast majority of whom live in developing countries (FAO et al. 2013). The international development community usually measures hunger and undernutrition in terms of food security, which is determined by assessing four indicators related to food and nourishment: availability, access, utilization, and stability. Food security is not achieved until a household can meet all four of these requirements in terms of its food intake.

In recent years, gender has been identified as an integral part of food security interventions for a number of reasons. Women and girls are among the most vulnerable to hunger and malnutrition, and at the same time, they are assuming a greater role in global agricultural production (FAO et al. 2013; FAO 2011). Yet women, including female farmers, face discrimination due to culturally and socially constructed stereotypes of gender roles, impeding their ability to farm as effectively and productively as their male counterparts. The challenge for governments and international development workers thus becomes protecting and promoting women's nutrition while simultaneously empowering women to produce higher agricultural yields for both household consumption and economic gain.

Due to the high concentration of food insecurity and gender inequality in poor, developing countries, most large-scale interventions (e.g., Millennium Development Goals) are targeted at these regions, particularly Asia and sub-Saharan Africa. Although food insecurity and gender inequality affect populations everywhere, this entry will similarly focus on the context of the developing world.

Background

The formal definition of food security, which emerged from the 1996 World Food Summit, is as follows: "Food security exists when all people, at all times, have physical and economic access to sufficient, safe and nutritious food to meet their dietary needs and food preferences for a healthy and active life" (FAO 1996). Although the

experience of food (in)security is often subjective – varying between households, countries, and cultural contexts – the international development community measures food security in terms of availability, access, utilization, and stability. Generally, a household is considered food secure if food is *available* to it in the region, it has physical and/or financial *access* to the food that is available, the food is culturally appropriate and *utilized* within the household so that all members' dietary needs are met, and all three of the above conditions are *stable* over time.

Women are essential to securing the *availability* and *access* components of food security in their households and communities: on average, they comprise 43% of the agricultural workforce in developing countries (FAO 2011). However, women's potential agricultural yields are stunted by socially and culturally constructed gender roles – assumptions about men and women that dictate allocation of assets and obligations (FAO 2011). Fortunately, because stereotypes about gender are socially constructed, it is possible to reshape gender roles over time through collective action, public policy, and a number of other cultural influences. The Food and Agriculture Organization of the United Nations (FAO) estimates that if women are given the same access to agricultural production resources as men, their yields would increase by 20–30%, in turn increasing agricultural output in developing countries by 2.5–4% and reducing the amount of hungry people in the world by 12–17% (FAO 2011).

Women are also essential to the *utilization* component of food security. In addition to being responsible for preparing meals, women are the primary caretakers of children, as well as family members who are elderly or chronically ill. Numerous studies have shown that in comparison to men, women spend a larger percentage of income on food (Akanji 2013). Consequently, in households where women control the budget, family members have better nutrition levels and childhood survival rates increase by 20% (UNGA 2012). This higher quality of care

that women provide, particularly to children, thus improves the health of future generations (FAO et al. 2010).

Given these figures, it is clear that empowering women with the resources they need to increase agricultural production and reshaping gender roles to give women more bargaining power within the household will improve global food security.

Gender Inequality in Agriculture

Gender inequality in the agricultural sector manifests in several ways. One of the greatest disparities between male and female farmers is land ownership. Recent figures from the FAO indicate that women own, on average, only 15% of land in developing countries, falling as low as 5% in Oceania, North Africa, and West Asia (FAO 2011). This significant inequality in property rights creates barriers for women not only in terms of agricultural production but also when attempting to obtain loans – a process that often requires formal proof of land ownership for collateral. Without the security of land tenure, women are also less likely to experiment with innovative farming methods and technologies (a problem compounded by their inability to access lending services). In the absence of formal ownership and inheritance rights, women are also less likely to act as stewards of their land by taking actions to improve soil fertility and biodiversity to preserve the soil for future farming (IFAD 2012).

Gender inequality extends from subsistence farming to large-scale commercial farming as well. Women's access to tools and resources necessary for expansion into commercial agriculture is limited, including access to improved seeds, fertilizers, pesticides, and other agricultural inputs, as well as agricultural extension services (e.g., training and farmer field schools) and commercial markets. These inputs are needed to increase yield and minimize labor on large plots of land, and extension services ensure that farmers access new technology and farming methods to improve efficiency. Men are typically the

beneficiaries of these resources and services, leaving women dependent on rainfed agriculture – a slower, more labor-intensive farming method that is also more vulnerable to climate shocks (IFAD 2012).

Women are also limited by their education levels, which are significantly lower than men's in nearly all developing countries (FAO 2011). In poorer households, girls are often removed from school earlier than boys when parents cannot afford school fees, usually because gender stereotypes dictate that education is more valuable for boys than girls. In countries where women face discrimination in their reproductive rights, they are often expected to marry and begin bearing children at an early age, suspending their formal education as a result. Education levels have a positive correlation with agricultural production, income, and nutrition in a household (FAO 2011). Higher levels of formal education allow women to seek additional economic opportunities outside the agricultural sphere, further contributing to household income and strengthening women's bargaining power within the family unit. Current research shows that improving women's education is in fact the single-most influential factor in improving a household's food security (UNGA 2012).

One of the greatest constraints on women's farm production is time poverty. In addition to agricultural work, women are also responsible for household duties including caregiving for children, elderly, and sick members of the family, fetching wood and water, preparing and serving meals, and a number of other domestic tasks. Women often assume these roles in part because of sociocultural expectations about gender and also due to the fact that they have less economic independence and bargaining power within the family. This unpaid domestic work is commonly referred to as the "care economy," and it requires a substantial amount of women's time, especially in developing countries where social programs to assist in child and healthcare are largely absent. Time-use surveys indicate that when the care economy is incorporated into time measurement, women work considerably longer hours than men, shouldering up to 90% of the time spent on food preparation (FAO 2011).

Feminization of Agriculture

The abovementioned gender inequalities in the agricultural sector compound the threat of food insecurity due to a growing trend called the "feminization of agriculture." As developing countries become more industrialized, the agricultural sector becomes highly concentrated, commercialized, and export-driven. What was once a collection of small-scale family farms shifts to large-scale, export-driven farming operations (DeSchutter 2013). A mass rural–urban migration usually accompanies this transition as rural agricultural workers trek to urban centers to seek work as waged laborers on commercial farms or to find employment in other sectors. The overwhelming majority of these rural–urban migrants are men, in part because of gender expectations and also because they have the education levels required to seek diversified employment opportunities, as well as fewer time constraints. Women are left in rural areas tending to the household and the family farm, triggering a pronounced increase in the percentage of female agricultural workers in comparison to men (Agarwal 2011).

In addition to assuming the responsibilities of subsistence farming from their male counterparts, some women also begin farming to produce food for markets (DeSchutter 2013). Here, the limitations women face in terms of land ownership, access to inputs, education, and time constraints can have significant impacts on farm productivity. Without the collateral needed to secure loans, women cannot purchase the inputs needed to increase agricultural yields. Raising livestock, including chickens and dairy animals, presents another opportunity for women to gain capital in agricultural markets. Women make up approximately two-thirds of livestock keepers, and the practice offers an appealing alternative mode of income generation in countries where women's land rights are restricted (FAO 2011). However, much like traditional land-based agricultural activities, time required of the care economy limits women's ability to manage the same quantities of livestock as men. Their working hours are restricted, as is their ability to travel to markets to sell goods. As their farm and livestock enterprises

scale up, women are often forced to relinquish control of operations to men, who are more likely to have the time and financial resources required to manage a larger business. If women are to remain essential to agricultural production, these obstacles must be removed to ensure they reach production levels required of their households, communities, and regional markets.

The feminization of agriculture also occurs outside the realm of subsistence and small-scale farming. In comparison to men, only a small portion of women in developing countries seek employment for wage, but those who do are more likely to work on farms than in any other sector. In Asia and sub-Saharan Africa, between 60% and 70% of female wage earners work in the agricultural sector (FAO 2011). As countries develop and agriculture becomes more commercialized, women will find more opportunities to work for wages on large-scale industrial farms (DeSchutter 2013). Here, they face a new host of issues including widespread discrimination among waged agricultural workers, hazardous working conditions, and exploitation due to their minimal bargaining power. Without the education needed to pursue other employment opportunities, women are left with few options in the labor market, and in the agricultural sector, they are often forced to settle for low-paying temporary or seasonal work (DeSchutter 2013). Gender stereotypes can also prevent women from obtaining higher-paying jobs along the supply chain, stifling their opportunities to advance in their careers (FAO 2011).

Gender Empowerment in Agriculture

Because of these gendered restrictions, women are circumscribed to low-productivity agriculture and their yields are consistently lower than men's. However, a number of studies have shown that this discrepancy in output levels is entirely attributable to women's restricted access to land, inputs, technology, extension services and labor, as well as time restraints due to the care economy (Agarwal 2011). Some studies suggest that without these gendered constraints, female farmers

would produce *higher* yields than men (Agarwal 2011). Using data from the OECD's Social Institutions and Gender Index, the FAO found that lower levels of gender inequality correlate positively with higher average cereal yields (FAO 2011).

As the proportion of women in the agricultural sector continues to rise, their habitually lower production levels have serious implications for the future of food availability in developing countries. Eliminating gender inequality and empowering female farmers thus becomes imperative to increasing agricultural outputs and achieving food security in these areas.

Empowering women in the agricultural sector will require a number of institutional, social, and cultural changes, perhaps the most important arising from the reinforced perception of women's capabilities and responsibilities in the agricultural sector. In countries where they are viewed more as helpers than farmers, women face more difficulty in accessing the resources and services needed to improve their yields (Agarwal 2011). This type of cultural shift can be challenging to execute, but with the help of gender-specific farm policies and programs, as well as coverage in the media, stereotypes and misperceptions of gender can be challenged and overcome (Agarwal 2011).

First, state and local governments need to amend land ownership and inheritance rights to allow women to purchase and inherit property in the same manner as men. In many developing countries, the formal rights to land titles within a household are customarily given to the men. Traditional patterns of land inheritance similarly benefit men over women; throughout Asia, Latin America, and sub-Saharan Africa, parents favor sons over daughters when passing down land, while local chiefs and community leaders typically allocate land to men under the assumption that it will be shared with female family members (FAO 2011). Even in countries where women are given the same legal rights to inheritance and land ownership, they often face an uphill battle in exercising these rights due to flawed legal structures and persistent gender bias toward men (Agarwal 2011). The change will need to come first within national land rights

legislation – ensuring equal ownership rights to men and women – followed by reform in legal implementation and customary law. The latter can be achieved with the help of community leaders and collective action by women themselves (FAO 2011). Educating both women and men about their land rights will be imperative to sustaining these changes, a task which both governments and NGOs can undertake.

Second, women need to be given equal access to farm inputs, extension services, and training. In most cases, modern farming technologies (e.g., improved seed varieties and fertilizers and the knowledge of how to properly plant and apply them) are disseminated by farm extension agents – public sector employees who make on-site visits to farms or farmer cooperatives to educate agricultural workers. The majority of extension agents are male, which poses several problems for female farmers. In some cultures, it is considered inappropriate or taboo for a male to meet socially with a female, especially if she is unmarried or widowed (FAO 2011). Male extension workers are also less aware of the constraints and knowledge gaps specific to female farmers and therefore may not address those issues. Because men have fewer domestic obligations, they are usually the household members who meet with agricultural extension agents, under the assumption that they will then pass that information on to the women, which is not always the case (UNGA 2012). In order to reach more women through extension services, governments and NGOs should make a concerted effort to hire more female extension workers and to train male extension workers on the specific needs of female farmers (FAO 2011).

Third, research and development (R&D) on improved agricultural technologies with respect to women's needs will contribute to higher output levels on female-tended farms and improved household food security. The first step in this process is identifying women's priorities and constraints. For example, women are generally limited by the labor intensity of certain crops, both because they typically cannot hire additional labor and because their own on-farm time is limited. Developing farming systems or mechanizations that minimize farm labor can increase women's

productivity tremendously (Meinzen-Dick et al. 2010). Women also have different priorities in terms of the types of crops they choose to produce. Whereas men are often responsible for high-input, high-yield cereal crops that meet the market demands of capitalized agriculture, women are more concerned with the ease of preparation, nutritional content, and taste of the food they harvest (Meinzen-Dick et al. 2010). Most R&D efforts are gender-biased toward men, as the primary objective is increasing yields of commercial crops. For agricultural research to benefit women, it is imperative that researchers consult with female farmers to determine the gender-specific needs that can guide future research (Meinzen-Dick et al. 2010). Women farmers are also valuable sources of climate- and culture-specific agricultural knowledge that researchers may otherwise never uncover (Meinzen-Dick et al. 2010).

Fourth, making capital available to women, typically through microfinance programs, will provide them with the financial resources they need to enter into market-based agriculture or pursue other business endeavors. Formal financial services (e.g., savings, loans, and credit) are usually inaccessible to the poorest populations in developing countries and even more so for women (UNDESA 2009). Yet access to credit and savings is essential for women's empowerment – it affords them bargaining power within the household and can serve as a contingency fund during periods of food insecurity. Microfinance programs are usually administered by NGOs, offering small-scale loans to poorer clients. Many are targeted specifically at women, who have a higher rate of loan repayment than men (UNDESA 2009). These lending programs are only effective, however, when accompanied by financial literacy education for women, teaching them how to make the best long-term investments (DeSchutter 2013). Research has shown that in some cases, male household members take advantage of women's preferred status as loan recipients and use their wives to obtain loans for their own purposes (DeSchutter 2013). Therefore, in communities where female-targeted microfinance programs are implemented, male household members should similarly receive

sensitization training on the importance of supporting and allowing women to control loans (DeSchutter 2013).

Finally, promoting female farming cooperatives will give women more leverage to apply for loans, pool resources to obtain agricultural inputs, and use collective action to affect gender-equal programs and policies. Farming co-ops can take many forms. Some are social groups that meet for educational purposes, often in the company of an agricultural extension agent who can teach co-op members about effective farming tools and methods. Others function as a group farming system, in which a collection of individual female farmers works together to produce crops for agricultural markets. The benefits of group farming are extensive: women can consolidate finances to buy input and equipment for the collective, increase production and profits by reducing time and costs, access formal loans and credit with greater ease, spread the risk associated with climate and price fluctuation over a larger group, and increase bargaining power with government agencies (Agarwal 2011; DeSchutter 2013).

Of course, this is not a comprehensive list of suggestions for empowering women as agricultural workers and should not be treated as such. As mentioned above, formal education and redistribution of tasks in the care economy are also necessary for women to garner more bargaining power in the household. Moreover, all of the suggested reforms must be met with a shift in the cultural perception of gender roles that no longer discriminates against female members of society.

Ethical Issues in the Feminization of Agriculture

Although researchers and international development professionals unanimously agree that empowering women and eliminating gender inequality in the agricultural sector will improve global food security, these sociocultural transformations do not come without additional challenges. In a recent paper, the UN Special Rapporteur on the Right to Food Olivier de

Schutter highlights the dichotomies that arise from the feminization of agriculture, both on the household subsistence level and in commercial agriculture (2013).

First, while many of the proposed programs and policy changes outlined in the previous section are intended to make homestead farming more efficient and productive for women, they also run the risk of perpetuating the gender roles that have kept women in the domestic sphere up to this point (DeSchutter 2013). Many of these support programs do little to expand the choices available to women outside the home; instead, the programs make women's current farming operations more productive while the onus of household food security and the care economy remains on the female head of household.

Some of the suggested interventions, notably microfinance and lending programs, do have the goal of "emancipating" women from subsistence farming to participate in market-based agricultural operations (DeSchutter 2013). Unfortunately, when women leave the home to work in a capitalized system of farming, they may simply be transitioning into a new cycle of exploitation in which they are beholden to long hours and low wages and sometimes enlisting their children to help make output quotas for commission (DeSchutter 2013).

DeSchutter identifies opportunity as the key force behind female empowerment. Neither subsistence farming nor commercial agriculture and wage labor should be the default option for women farmers. They should have the freedom, both in legal and cultural respects, to make a choice about their futures, whether on or off the homestead (2013).

Summary

On average, women comprise 43% of the agricultural workforce in developing countries, making them essential to global food production and food security. However, socioculturally constructed gender roles prevent women from reaching their full potential as producers. Gender stereotypes limit women's access to the tools, technology,

knowledge, financial resources, and time required of market-based farming. As the proportion of women in the agricultural sector increases in comparison to men, a number of ethical questions arise about how women should be supported in both subsistence and commercialized agriculture.

Introduction

Hilde Lindemann (2000) points out that philosophical theories are often based on a flawed picture of society in which the private sphere is utterly isolated from the public sphere – a distinction going back to John Stuart Mill – and what is done in the private sphere is often erroneously considered not fit subject for issues of ethics or justice, certainly not of politics. A classic example is that caregiving by family and friends is seen as a matter of personal obligation but not of justice or politics (feminist treatments of dependency work critique this stance). Like caregiving, many food behaviors occur within this private sphere as people cook meals, grow vegetables in small gardens for supplementation or subsistence, consume meals, or

keep food animals for subsistence use or informal trading of eggs and milk. Such “private” food behaviors occur in every society, in both urban and rural settings in the global north and the global south, and are often performed by women. By comparison, food production and preparation which occur within the public sphere – on farms, in restaurants, and so forth – are far more visible and more easily counted and acknowledged in economic calculations (Waring 2004).

Food behaviors, both private and public, are deeply affected by gender norms concerning both masculinity and femininity. In some ways, food-centered activities constitute gender relations and identities across cultures (Counihan and Kaplan 1998). This entry provides a non-exhaustive overview of how gender norms bear on food behaviors broadly construed, focusing on three categories: food production, food preparation, and food consumption.

Food Production

Food production can differ widely in various economic settings within and between nations. Gender norms governing control and ownership of business, as well as roles in policy-making, routinely mean that even women who are engaged in agricultural work in the public sphere have little say in its conduct. Those engaged in agricultural work in the private sphere, through the use of home gardens for supplementation or subsistence, find their work to be invisible to standard economic measures (Waring 2004).

Carolyn Sachs warns against overgeneralization about rural women involved in agricultural work, noting that they are diverse in race, class, ethnicity, and sexuality. Yet, she argues rural women do suffer from institutional subordination in agricultural work around the world. State agricultural policies regarding domestic and foreign programs have typically supported what she describes as “patriarchal family farms” through extension loans, government loans, development aid, and marketing policies (Sachs 1996). These farms, for good or ill, have been disrupted as large-scale industrial agriculture increasingly provides for the

food production needs of domestic and global markets. Sachs argues that this will not necessarily benefit women, however, because – as with so many corporate structures – few women hold positions of power in agro-industries (those who do are likely to be those whose race and class already provide them privilege): “Rather, such systems tend to exacerbate class, ethnic, and racial differences and privileges in rural areas and often rely heavily on the cheap labor of working-class people, especially racial and ethnic minorities” (Sachs 1996).

Such commercial work, being conducted in the public sphere, at least receives economic valuation even as it tends to benefit men more than women and some women more than others. Supplemental food production – backyard vegetable gardens or the keeping of chickens for eggs – and subsistence farming are utterly invisible to traditional economic measures (Waring 2004). As Sachs (1996) notes, studies on sub-Saharan Africa report that women produce roughly 80% of the food and provide household water by transporting it from pumps, wells, or waterways. Though critical to family welfare, subsistence farming remains invisible economic-based policy measures. Since gender norms dictate that “private” food production be done overwhelmingly by women – carrying water in particular is seen as work for women and girls – their role in food production is often simply irrelevant to those in power even as it is deeply relevant to their families. Meena Bigli attests that 70–80% of the Pacific Rim’s working women work in the agricultural sector, yet many countries continue to focus on men as planners and decision-makers for agricultural policy and problem-solving, nor are women targeted for capacity building and education in the sector (Report of Women Major Group 2007). Similarly, Signora Maria Francisca de Belo Assis noted that rural women farmers in developing nations such as her own Timor-Leste need to compete in the market economy but do not have adequate information and are not included in decision-making. She argues that this is necessary in order to make rural and sustainable development a reality (Report of Women Major Group 2007).

In the United States, there is a movement to bring more women into agricultural work as business owners, especially in the sustainable food industry. However, even this is fraught with gender norms. Costa (2010) carefully notes that women have long been underrepresented in the public sphere with respect to agriculture despite the work they do at home and outside the home with respect to food production, planning, and preparation. Women indeed do a great deal of work on food production, both as farmers and advocates, comprising 61.5% of the employees and 60% of the executive directors of the top 15 American nonprofits focusing on sustainable agricultural issues. And yet, it is gender norms that drive the success of women in this field: by way of explanation, Costa (2010) notes that women are mothers of children, are nurturers of health, and have the largest impact and concern when it comes to what they feed themselves, their families, and the wider community.

Sustainability has come to be seen as an appropriate women's issue, as has the quality of crops and meats. While this increases women's involvement in agricultural policy, it too is based on gender norms. As Marilyn Frye (1983) points out, women's anger and passionate concern are most likely to be given uptake when it falls within an appropriate, gender normative sphere of concern. With respect to agriculture, concerns over food safety for women's families, and the condition of the world left behind to their descendants, are just such concerns.

Gender norms often keep women from economically and politically powerful positions in the public sphere of food production despite their work in both public and private food production. Exceptions most often occur when the ways in which women seek power over food production line up nicely with gender norms about their proper role in caring for others.

Food Preparation

Food preparation, like food production, is structured by the flawed private-public divide. Though reinforcing that divide is problematic, it is useful

to point out how that divide plays a role in the way that both masculine and feminine gender norms shape food preparation behaviors. On the private side, we have home cooking and service cooking by volunteers working in community settings such as churches or food charities. On the public side, we have commercial cooking performed in restaurants, hotels, and schools. Gender norms affect food preparation.

Home cooking is a loaded activity in Western cultures and around the world, often heavily gendered (Reiheld 2008). It is often considered women's work and feminized according to gender norms, seen as properly the duty of women; where home cooking is acceptable for men, it tends to be masculinized or is seen as a "favor" or supererogatory. An influential review paper of research on gendered division of household labor in America found that nearly two-thirds of total housework hours are spent cooking and cleaning, work which continues to be – and to be seen as – much more often the purview of women than men (Bianchi et al. 2000). Both cooking and grocery shopping show similar patterns in many studies and many developed countries (Lippe et al. 2011), including the Anglo-heritage countries such as Australia, the United Kingdom, and the United States (Dixey 1996; Breen and Cooke 2005). In particular, highly educated and married women in masculine cultures do less paid work and more housework such as cooking than do their counterparts in more feminine cultures (Lippe et al. 2011).

This gendering of cooking as women's work begins early in American culture, as the division of children's chores shows: in families with both boy and girl children, girls are more likely to be assigned cooking and cleaning chores while boys are more likely to be assigned maintenance chores such as mowing the lawn or repairing things or taking out the trash. Both children's and adult's divisions of household work in the United States follow gender lines, and both children and adults generally do not question such stereotypical divisions (Schuette and Killen 2009), no less so with cooking.

This goes beyond Europe and Anglo-heritage countries. In 1974, O'Laughlin (Furst 1997)

reported that in many non-Western societies, men did not do the cooking and had never learned to cook because doing women's work was considered shameful. In one society, cooking was defined explicitly as women's work, and the pots as women's tools, so much so that men were looked upon as no longer men if they used the cooking pots.

However, in Europe and the Anglo-heritage countries, there are certain kinds of cooking that are gendered masculine. One of these is barbecuing outdoors on a grill or an open flame, especially when cooking heavy meats such as steak. In America, men often take great pride in being good at the grill, as depicted in numerous television ads, but are rarely depicted doing the regular cooking which tends to be gendered feminine.

Regardless of how often gender norms dictate that men should occasionally cook, gender norms also still hold women responsible for the nutritional status of their household. However, doing so ignores how deeply access to food, cooking skills, and cooking time are situated in class, culture, race, and gender. Nowhere is this more apparent than in public health campaigns over obesity and childhood nutrition. Breastfeeding campaigns by the Department of Health and Human Services in the United States, for instance, use slogans such as "breast is best" and, more recently, "babies were born to be breastfed." As Rebecca Kukla has pointed out, the strategy of such campaigns focuses on women as the only relevant moral agent who needs to be convinced; if only such campaigns could reach women, it is assumed they would change their behaviors. Yet, women are overwhelmingly aware of the evidence that babies are healthier when breastfed. Kukla points out that this underlying assumption – that women simply haven't been convinced yet – ignores the vast array of constraints on women's lived experience that restricts their ability to breast-feed, including but not limited to lactation difficulties, workplaces which do not allow adequate maternity leave or facilities to pump breast milk, social stigma against public breast-feeding, and lack of safe spaces in which to breastfeed. Kukla argues that "there are many American women, especially women from the socially

vulnerable groups least likely to breastfeed, for whom breastfeeding is not in fact a livable choice" for reasons that go beyond barriers to the very culture that is in fact asking women to put their babies' nutritional needs first (2006). This has potential bearing on UNICEF's initiatives to increase breastfeeding globally, some of which attempt to involve those around mothers rather than aiming squarely at mothers.

Breastfeeding is not the only way in which women are held responsible for the family's nutritional status, however, especially in the context of rising obesity rates in both the global North and South. A quick survey of articles published on children's nutrition shows that those addressing mothers consider food preparation (and the mother's own food consumption) as well as maternal income, whereas those considering fathers solely or as well as mothers focus on paternal income's impact on the nutritional status of children. In the United States, women still make the primary healthcare decisions in two-thirds of American households and are primarily responsible (in two-parent heterosexual marriages) for making the kids' doctor appointments and conveying them to and from appointments. This responsibility for family health in general is consistent with what Joan Wolf (2007) calls an ideology of "total motherhood" in which mothers are held responsible for any harm that may befall their children. This extends to nutrition, at which point the family becomes the site of intervention with women responsible for that intervention (Lupton 2013), and not only in the United States. In the 1990s, children in Nepal faced widespread vitamin-A deficiency which can have serious health consequences. Health experts recruited grandmothers – who had time to get the pills out and authority to make sure they were taken – to distribute nutritional supplements. As of 2005, 48,000 grandmothers distributed vitamin A to 3.5 million Nepalese children. Development agencies often give resources or money for children's health to women in the family, knowing or suspecting that men are more likely to spend it on themselves (Kluger 2010). Dixey (1996), writing about nutritional programs designed to teach healthy cooking and eating skills in the face of

rising obesity, cautions against targeting only women and girls with opportunities to learn how to provide healthy food lest cooking skills come to be seen as part of an attempt to re-create traditional gender roles.

Such attention to women as responsible for family health has obvious pragmatic benefits, since dominant gender norms mean they are best situated to improve family health. As with breastfeeding, however, this general responsibility ignores the situatedness of women's decisions about food acquisition and preparation. Aphramor and Gingras (2009) note that dieticians who advise patients and caregivers on improved eating focus overwhelmingly on "eating plans" and individual agency over them when assisting women in combatting obesity for themselves and their families. This individualistic approach, they say, conserves a "limited, consumerist, and decontextualized understanding of health and fatness in which issues of power, inequity, and gender remain peripheral and occluded," creating a "theoretical desert" with little real hope of achieving health. As an example, we might consider the limited access many Americans have to fresh fruit and vegetables, as exemplified in the US Department of Agriculture's conception, and maps of "food deserts," areas in which access to food is restricted to prepared food and very little fresh food. Abigail Saguy (2013) notes that our assessment of women as food preparers in the private setting is deeply embedded in race and class. She gives the example of Katherine, a young anorexic white woman whose mother drops everything to whip up a three-course meal if Katherine says she is hungry, an example we often view approvingly. However, by contrast, a poor black single mother may lose custody of her son as he gains weight despite her best efforts to take him to the Y and ensure he eats healthy food whenever she can watch him given her time-consuming minimum wage job. As Saguy notes, the white family is considered to have a daughter with a terrible illness while the black family is treated as having a son who suffers from neglect (Saguy 2013). Such assessments are insensitive to class concerns and race issues, especially given the vast disparities in time and resources. Lack of attention to issues of

class or geography inappropriately places blame for unhealthy food preparation on individuals who, because of gender norms governing food preparation, are overwhelmingly women around the world.

It is not only nutritional status for which women are held responsible when it is assumed they cook but the very nature of the family. Anglo-heritage nations have long – but not always – depicted cooking, and housework more generally, as a source of feminine virtue and a duty to family (Reiheld 2008). Recent rhetoric over family values in the United States has urged families to have more sit-down meals, on both public health and moral grounds. With respect to the latter, it is claimed that families are more functional, and a flourishing and good life more attainable, when family members have dedicated time together without the interruption of television, telephone, or portable computing devices. The burdens of preparing sit-down meals fall on women, whom we have seen are generally held responsible for meals the world over. Indeed, a large survey of British women found that they had adopted the norm that "the proper meal" confirms the family as a "proper family" and is, by definition, made by the wife (Furst 1997). In such ways are the norms of domestic femininity often constituted by food behaviors.

Reinforcing the importance of the private-public divide for how cooking is evaluated, Furst notes that cooking may be understood as an expression of "a rationality of the gift," in which the production of use-values in the home is seen as a gift to loved ones. It should be noted that this notion of cooking as a gift makes it a private matter nearly immune from critiques of fairness which might be levied on an exchange of goods or services that takes place in the public sphere. By contrast, Furst presents "the rationality of the commodity" which governs production in the market. Since food production in the home, still largely performed by women due to gender norms, has no market valuation for reasons discussed by Waring (2004), this form of "women's work" has far less social value than cooking performed in the public sphere which is visible to markets. That work, while sometimes

performed by women, has high-status variants in the form of professional chefs. Chefs and heads of staff in commercial kitchens remain overwhelmingly men. As Furst puts it, when men do the cooking, it is mainly public cooking, the food of money and prestige. It is important to add to this, however, the above-noted fact that when men do home cooking in the private sphere, it is more often than not highly masculinized with fire, meat, and so forth.

Gender norms strongly affect food preparation behaviors, in ways ranging from division of this labor to holding women responsible for the health of their families and whether the family is a good one. Gender norms also relegate women's food preparation predominantly to the private sphere, while men's food preparation is masculinized, often higher status, and generally in the public sphere.

Food Consumption

Food consumption behaviors are no less governed by gender norms than food production or food preparation. And since everyone eats – though not everyone produces and prepares food – food consumption behaviors are perhaps the area in which it is easiest for most people to see how their behaviors are affected by gender norms.

Perhaps the most obvious way is with dieting. Sandra Bartky (1998) influentially describes femininity, and its associated gender norms, as a “disciplinary regime” governing the state of feminine bodies, requiring training so as to achieve normative shapes and habits. She questions the public-private divide and argues that where gender norms – especially those of femininity but also of masculinity – are concerned, there is no real distinction between the public and the private: we must keep in mind that the Second Wave feminist slogan “the personal is political” applies also to the “production of the ‘properly’ feminine subject” (Bartky 1998). Dieting is, for Bartky, a paradigmatic disciplinary practice of femininity. If we take dieting out of the Western context of striving for taut, small-breasted, and narrow-hipped bodies, it can apply to any disciplinary form of eating in

order to achieve whatever the feminine norm might be even if that norm is the large-bodied “traditionally built lady” of Botswana described in Alexander McCall Smith's popular No. 1 Ladies Detective Agency novels. The goal of dieting, regardless of the specific body-shape norm, is of a “properly” feminine body.

Bartky noted a still-true fact that the majority of American women and girls – and an increasing percentage of men and boys – report being on a diet at any given time. One might attribute this to health concerns in a world with increasing obesity except that diet products and even public health campaigns routinely urge smaller bodies rather than healthy eating, and media are filled with promises of rapid weight loss rather than improvements in cholesterol, diabetes risk, or other health indicators. Dieting to restrict calories, as Bartky says, “disciplines the body's hungers: appetite must be monitored at all times and governed by an iron will.”

Persons who appear to have “failed” at this discipline, who have bodies too fat by some standards or too thin by others, are regarded as actually unable to control their own appetites; as Susan Bordo says, the overeater becomes a libertine (Bartky 1998). Abigail Saguy (2013) illuminates how class and race further complicate such judgments, arguing that stereotypes of African-American women as having unbridled appetites inform discussion of their food consumption and body weight. Drawing a wall of separation between the disciplined and undisciplined disrupts the possibility of social solidarity between women of different body types, and to the extent that fat people are also poor minority women, discussions of irresponsible “fatties” shore up prejudices against women of color (Saguy 2013). It is worth noting that in cultures where larger, even fat, bodies are considered the feminine ideal, it is in part precisely because access to more calories allows such a body to be produced. Access to more calories, and the discipline to consume them no matter your body's own signals, then indicates both discipline and relative wealth. Gendered expectations for bodily discipline, shaped also by race and class, make failures of those whose bodies appear undisciplined.

While men are far less subject to the need to discipline their bodies with respect to norms of masculinity, nonetheless, this does affect men. Achieving the masculine body norms of visible muscle tone and definition can require dieting, but most certainly requires not only exercise but a certain kind of exercise aimed at producing a certain kind of musculature. Masculinity, too, is a disciplinary regime aimed at producing the “properly” masculine body. For men as for women, lack of discipline becomes an individual failing.

Gender norms driving food consumption apply not only to body size and calorie consumption but also to what is considered appropriate for men or women to eat. Some elements of French culture view fish as inappropriate for French men to eat because the flaky texture of fish must be eaten in small mouthfuls and chewed gently in a way that contradicts French norms of masculinity (Furst 1997). Women in many Anglo-heritage and European nations are expected to eat salads; it has recently been noted that Internet image searches for a person eating salad are almost universally images of happy, laughing women eating salad. This means of consuming this particular food comports with culture-specific gender norms of self-discipline and feminine bodies. Examples of gendered foods abound, and social status is lost for men if they eat feminine foods in feminine ways, gained when they eat masculine foods in masculine ways. Women, by comparison, lose status by eating masculine foods in masculine ways and retain it by eating feminine foods in feminine ways.

As with self-control and will in food preparation – whether breastfeeding or family cooking – food consumption is deeply affected by norms about both bodies and foods, norms whose nature and application are highly gendered and deeply embedded in culture, class, and race.

Summary

The public-private distinction, though of dubious utility, plays a significant role in how gender norms govern the three food behaviors considered here: food production, food preparation, and food consumption. Norms of domestic femininity

are commonly constituted by food behaviors. The impact of gender norms on food behavior is often complicated by issues of culture, class, and race. Several gender norms are of particular importance, especially norms which make women responsible for others, specifically within the traditional private sphere, and gender norms which make women responsible for conforming their own bodies to ideal standards of femininity.

Introduction

Obesity is defined and identified in a number of ways, depending on whether it is in a medical, social, public health, or other context. Most commonly used medically is the body mass index (BMI) scale, which uses a formula based on the relationship of height to weight. On this scale, 19–24 is normal, 25–29 is overweight, and a BMI of 30 and above is defined as obese. A BMI of 40 and above is defined as extreme (also called morbid) obesity.

Medical and public health experts consider obesity to be a major health problem. More than 500 million people worldwide are obese, with more than 1.9 million considered overweight (Finucane et al. 2011). Obesity is a major risk factor for type 2 diabetes, and it is also linked to hypertension, cardiovascular disease, sleep apnea, infertility, and osteoarthritis, among other conditions (CDC 2011).

Although the standard medical account of obesity explains it as an energy imbalance – more calories are taken in than expended, resulting in excess weight gain – both its causes and effects are complex and multifactorial.

Obesity affects individuals in a variety of ways: medically, socially, psychologically, and economically, to name a few. Many of these effects are the result of what public health and other experts call “weight stigmatization.” Weight stigmatization is not just an aesthetic judgment of physical unattractiveness. It is about using those judgments about someone's weight to form conclusions about other dimensions of their lives (Hebl and Heatherton 1998). Studies on the effects of weight stigmatization are well represented in the social science, psychological, and medical literature. Across the board, these studies show gender differences in both the types and magnitudes of weight stigmatization; women tend to experience more weight stigmatization than men in virtually all social contexts, and the effects on them tend to be more extreme and longer lasting.

After a brief primer on obesity, its causes and effects (and in particular its gender-based effects), this entry will examine weight stigmatization in

more detail, giving an overview of some of the major results of studies across social science and public health fields. Next will be a discussion of two main approaches from which to understand and address effects of weight stigmatization. Two common approaches – those pursued by public health ethicists and by various feminist scholars – overlap in some ways but differ substantively about the nature and medical status of obesity. Finally, this entry summarizes responses to issues of obesity and gender from the standpoints of both ethical approaches. There is a growing consensus across disparate groups about how to understand obesity as a social phenomenon, how to address it, and even how to reconceive health and fitness in ways that underplay the importance of body weight.

Obesity: Its Causes and Effects

Currently, the most common way to determine obesity is the BMI (body mass index) scale, which is calculated by taking a person's weight in kilograms and dividing it by the square of his/her height in meters. The resulting numbers fall on a scale in which below 19 is underweight, 19–24 is normal weight, 25–29 is overweight, and 30 or higher is obese. There are classifications for higher BMI values within the obesity category: 35–40 is class II or severely obese, and 40 and above is class III or very severely obese. BMI is the standard used both by the World Health Organization and by the Centers for Disease Control in the United States. Some gender- and race-specific BMI scales have been proposed, but most health organizations use the standard scale. A separate BMI scale is used for children.

According to 2009–2010 data in the United States from the Centers for Disease Control (Fryar et al. 2012), 33% of Americans are overweight, 35.7% are obese, and 6.3% are extremely obese. Breaking the data down by gender, we see fewer women overweight than men (27.9% vs. 38.4%), women with about the same obesity incidence as men (35.8% vs. 35.7%), but with a much higher incidence of extreme obesity (8.1%

vs. 4.4%). Among Black and Mexican-American survey respondents, the gender differences are more pronounced. Black and Mexican-American women have a higher incidence of obesity than men (58.5% vs. 38.8% for Black respondents, 44.9% vs. 36.6% for Mexican-American respondents).

Causes of Obesity

Obesity has multiple causes – genetic, psychological, cultural, economic, and environmental conditions contribute in many ways to increased body mass in populations. Public health approaches to combating obesity have increasingly focused on features external to the individual as causes to target in proposed interventions, policy, or regulation. The built environment, availability and price of fresh fruits and vegetables, amount of food advertising, and access to fast food and sugar-sweetened beverages have been cited as factors that should be addressed at a governmental level in order to help reduce the incidence of obesity.

It is not clear which causes of obesity are gender specific, but income as a contributing social determinant for obesity seems to affect women more than men; studies show that income seems not to be a contributing factor for men, whereas women with incomes under \$75,000 are much more likely to be obese.

Effects of Obesity

Obesity is considered a major public health problem because clear links have been established between obesity and a number of adverse health outcomes, including hypertension, type 2 diabetes, cardiovascular disease, stroke, numerous cancers, osteoarthritis, and gall bladder disease (Kim and Popkin 2006). Suggested medical treatments for obesity range from dieting and exercise to bariatric surgery. Estimates of how many Americans are on a diet range from 45 to more than 100 million. Women are the vast majority of dieters (estimates vary from 50% to 85%). They also undergo more

bariatric surgery to treat obesity than men do – different studies estimate that at least 80% of gastric bypass surgeries are performed on women. Bariatric surgery carries with it the possibility of mortality, postsurgical complications, and other short- and long-term effects.

Studies have suggested many effects of obesity on women's fertility, pregnancy, and complications in childbirth. Obese women have higher rates of infertility, are at higher risk for hypertension and gestational diabetes during pregnancy, and have higher rates of caesarian sections and longer labors (Linne 2004). Obesity has been positively associated with depression for both women and men, but its relationship with suicide is still unclear. There is some evidence that extreme obesity (BMI >40) is more likely to be associated with suicidal thoughts and attempts in women than in men. With respect to the relationships between eating disorders and obesity, there is much evidence that women (young women in particular) are at higher risk for eating disorders and that body dissatisfaction can contribute to development of binge eating disorder, bulimia, or anorexia nervosa.

The most pervasive effects of obesity, according to most studies across disciplines, are those resulting from weight stigmatization. In the next section, weight stigmatization will be discussed, with a focus on its effects on women.

Weight Stigmatization

The effects of obesity are not limited to the effects covered in the medical literature. In fact, the most powerful and pervasive effects of obesity are due to weight stigmatization, according to experts in fields ranging from public health to gender studies. Weight stigmatization (also called obesity stigma, fat stigma, weight discrimination, or weight bias, henceforth referred to as weight stigma) is the formation of negative judgments about a person's character or personality traits based on observations and judgments about that person's weight. Weight stigma results in discrimination against obese people in virtually every social context; its effects are extremely well

documented by studies across social science and health fields in many countries.

A Sample of Research Findings on Weight Stigma

Weight stigma effects have been documented for virtually all social contexts of life; from education, work, and family to healthcare, overweight and obese people experience negative judgments from others that result in lower wages, less professional advancement, less access to quality healthcare, and lower overall life satisfaction. Research on weight stigma and its effects is conducted in all fields of social science as well as health and legal disciplines. Below is a brief sample of some of the results from current research.

Economic Effects of Weight Stigma

There is an extensive body of research on the effects of weight stigma on overweight and obese people, documenting a variety of economic effects and psychological effects. For some sample sources and bibliographies, see Baum and Ford (2004), Puhl et al. (2010a), Fikkan and Rothblum (2012), and Friedman and Puhl (2012).

In many studies, overweight and obese people are found to receive lower wages for the same position, fewer promotions than their non-overweight coworkers, and less desirable work assignments and experience lower hiring rates. In a survey of recent research by Friedman and Puhl (2012), they report that 54% of overweight workers reported being stigmatized by coworkers – negative judgments include being perceived as lazy, lacking in self-discipline and personal hygiene, less competent, less ambitious, and less productive.

Weight stigma effects for women in the workplace have been shown to be much stronger than for men. In one study about perceived job candidate desirability (cited in Fikkan and Rothblum 2012), participants were less likely to recommend overweight or obese female job

candidates than male candidates of similar weights. In other studies cited in the same paper, participants made no job-related distinctions between males of different weights, but made many discriminatory work-related decisions about heavier females.

Lost wages due to weight stigma are greater for women than men. Overweight or obese women earn less than non-overweight women (estimates range from 9% to 17% less; Fikkan and Rothblum 2012, p. 577). Studies also show that overweight or obese women near retirement age have an overall lower net worth than non-overweight women. This result contrasts markedly with men, for whom being overweight or obese is associated with higher net worth at retirement (cited in Fikkan and Rothblum 2012). Weight stigma workplace effects are also triggered at much lower BMIs for women than men (25 for women vs. 32 for men). Weight stigma in the workplace diminishes with years of work experience for men, but it persists throughout women's careers. At higher incomes, obese women are largely unrepresented: less than 10% of female CEOs have a BMI over 25, but more than 61% of male CEOs have a BMI over 25.

Weight Stigma Effects in Education

Studies on weight stigma in educational settings identify a variety of effects that are relevant both economically and psychologically for those experiencing weight discrimination. Overweight and obese adolescents are at greater risk of lower academic achievement and lower rates of social acceptance among their peers. These effects are, once again, much stronger among adolescent girls than boys. In one study, obese female high school graduates were shown to be less likely to go to college than their nonobese counterparts; the researchers found no such effects for boys. Studies have shown that college students with higher weights receive less parental financial assistance than those with lower body weights and found stronger incidence of this effect among overweight females than males. Psycho-social effects of weight stigma in adolescents

also appear to be stronger in females – those who perceived themselves as obese were more at risk for depression and lower grade point averages. This effect was not observed for adolescent males.

Weight Stigma and Effects on Mental and Physical Health

Weight stigma effects on health have been shown to erode physical and psychological health in a number of ways. First, those experiencing weight discrimination tend to receive less and lower-quality healthcare; a recent study of 400 doctors showed that one of three surveyed associated obesity with patient noncompliance, hostility, dishonesty, and poor hygiene (Friedman and Puhl 2012). Overweight and obese patients are more likely to cancel or delay medical appointments, including diagnostic screening tests. In surveys, more than 69% of overweight people reported being stigmatized by doctors (cited in Friedman and Puhl 2012). This effect is even stronger among overweight women; in one study, 83% reported avoiding appropriate healthcare because of their weight (cited in Puhl et al. 2010a).

Weight Stigma Effects on Dating and Marriage

The effects of weight stigma on dating and marriage are much stronger for overweight and obese women than they are for men of similar weights. Smith (2012) argues that a primary reason why weight stigma affects women so much more severely than men is that overweight and obese women are seen not only as lacking control but also as unattractive. Many studies show marked gender asymmetries in social penalties for obesity. Obese women have lower marriage and cohabitation rates than their nonobese counterparts. When they do marry, their partners tend to have lower levels of education and lower incomes. These effects were either less strong or not observed for men (cited in Fikkan and Rothblum 2012). Among adolescents, studies show that obese

girls are seen as less physically attractive, having a lower sex drive, and less warm than nonobese girls. Again, this effect was not observed for obese boys.

Obesity and Weight Stigma as a Vicious Cycle

There is a common view still present in popular discussions about obesity that stigmatizing obesity functions as a motivation for overweight and obese persons to lose weight. Stigmatizing weight, seen in this way, is like stigmatizing smoking, which has resulted in lowered incidence of smoking in the United States (see, e.g., Beam 2011). Potential merits of this strategy have also been argued for by bioethicist Daniel Callahan (2013), provoking considerable backlash from obesity researchers.

However, there is much scientific evidence to suggest that the abovementioned view is not true – that is, weight stigma exacerbates rather than diminishes the incidence of obesity (Sutin and Terracciano 2013). Weight stigmas can increase psychological stress, which itself can contribute to poor physical health and increased obesity. States of extreme psychological stress can activate physiological mechanisms governing appetite and satiety, contributing to increase food intake and abdominal obesity, the latter of which is a risk factor for type 2 diabetes (cited in Puhl et al. 2010b). Weight stigma also exacerbates eating disorders, often resulting in weight increases among obese and overweight people already suffering from discrimination. Studies have shown that among both women and men, internalizing weight stigma leads to increased risk of binge eating, higher calorie intake, and reduced exercise. Puhl et al. (2010a, p. 1023) note that research suggests connections between perceived weight discrimination and increased weight gain, glucose intolerance, and abdominal obesity. Among women, weight discrimination has been found to be the third most common source of perceived discrimination (after gender and age) – more so than race, sexual orientation, religion, or physical disability (Puhl et al. 2008).

Public Health and Ethical Ramifications of Weight Stigma

Scholars in science and humanities fields have provided varied and extensive analyses of some of the cultural and societal sources of weight stigma. Social science researchers have documented the prevalence of negative views and stereotypes about those who are obese, including blaming obese and overweight people for a lack of willpower or self-control. This is the case despite the fact that to date there has been little progress in developing effective medical treatments to bring about and maintain long-term weight loss. Many public health researchers (e.g., Puhl et al. 2010a) argue that weight stigma is a social justice as well as a public health issue. Historically vulnerable populations (e.g., low income and minority groups) are at greater risk for obesity and, because of income and health inequalities, also suffer disproportionately from many of the effects of both obesity and weight stigma. Groups that already suffer from racial, sexual, and other forms of discrimination have been harmed in measurable ways by the pervasive effects of weight stigma. Friedman and Puhl (2012) argue for the need to develop federal, state, and local laws and policies specifically prohibiting weight-stigmatizing practices in business, schools, healthcare facilities, and all levels of government. Public health ethicists have long argued that disease stigma results in harms to vulnerable populations (especially in cases of alcoholism and HIV/AIDS) and has blocked advancements in prevention and treatment. Enacting legislation, regulation, and policies designed to protect overweight and obese people from the harmful effects of weight stigma is, in their view, a basic human rights issue.

Gendered Judgments, Fat Bodies, and Weight Stigma

Feminist scholars have long argued that weight stigma against women takes place within cultures obsessed with thinness as an ideal (Orbach 1978; Bordo 1993). Since the publication of these early

groundbreaking works, many scholars have pursued arguments that reveal inconsistencies in the ways norms about body weight, health, and social equality have been conflated and leveraged against women. Saguy (2013) objects to the ways obesity has been pathologized and demonized in Western societies. Noting the lack of effective medical treatments for obesity and scientific evidence that fitness and health do not equal lack of fatness, she argues for a reframing of conceptions of body size as more neutral points along a spectrum. Her position is embraced by many obesity support and obesity rights advocacy groups like the National Association to Advance Fat Acceptance and Health at Every Size.

Fat studies – a recently developed field – engages in critical examinations of the origins and justifications for normative claims about body size in societies where weight stigma is common. Comprised of both social scientists and humanists, fat studies scholars like Rothblum and Solovay (2009) self-consciously blur the lines between academic and activist approaches to the social phenomena that underlie claims, theories, and practices surrounding body weight norms. In particular, fat studies scholars often situate judgments about fat bodies within a context in which political power is gained through marginalizing vulnerable groups (e.g., women, racial minorities, overweight and obese, LGBT, disabled) and creating a social and political “other” to be excluded. By endorsing liberation for these groups, fat studies scholars are advocating for political change, cultural shifts in how members of society are viewed and accepted, and a new set of expanded identities that embraces diversity.

The politics of fatness is not just at the individual level, according to feminist scholars, but also at the center of international commerce and geopolitics. In Vandamme et al.’s (2010, pp. 143–157) work, Wilkerson argues that cultural practices that enforce strict body ideals and pathologize heavier bodies are part of what she calls the Thin Contract – the body and its status (e.g., as fat or thin) are “central to determinations of sociopolitical inclusion.” She claims that any discussion of obesity and its effects is

shaped by political dynamics that span food production, labor, and global commerce. Her position is echoed by Lebesco (2004), who argues that fat is not a medical or aesthetic, but rather a political state of body; she entertains the idea that fat bodies are considered failed citizens, deficient in multiple ways and deserving of social rejection. Her response to what she sees as political injustice is to transform fat identity through community activism, aligning fat, queer, and disability groups for more effective and increased fat-positive messages.

Summary

Obesity is generally defined as an energy imbalance in which more calories are taken in than expended. The body mass index (BMI) scale is the most common way of measuring obesity. A majority of both women and men in the United States are overweight or obese, and to date there are few effective treatments for loss and long-term maintenance of weight loss. In addition to the physical effects of obesity, overweight and obese people are harmed by the pervasive effects of weight stigma in the workplace, in schools and healthcare facilities, and in social relationships. Women experience stronger and longer-lasting weight stigma effects than men, affecting them economically, socially, psychologically, and physically. Public health and feminist scholars agree that weight stigma is a violation of the rights of overweight and obese people and argue for a variety of ways to redress the harms that they suffer. Approaches vary, ranging from proposed anti-discrimination legislation to a reconceptualization of body identity.

Background

Anthropogenic genome modification of organisms has been occurring for thousands of years. Historically, the practice of selectively breeding plants and animals for preferred traits has greatly influenced both food production and animal domestication. However, selective breeding has various drawbacks. First, it may take many generations to produce the desired results. Second, certain traits may have naturally low heritability, severely impacting their ability to be selectively bred. Third, selectively breeding for certain traits has resulted in various diseases and deformities that are detrimental to animal health and welfare. Seen against the background of these drawbacks, the evolution of genetic engineering technologies has revolutionized the ways and magnified the ease with which humans can manipulate the genomes of animals.

Genetic engineering is the direct alteration of an organism's genetic material through use of biotechnology. Such alterations include cutting out DNA from an organism's genome ("knock-out"), inserting DNA into an organism's genome ("knock-in"), or modifying the level of expression of a gene (e.g., silencing). Genetic engineering of animals has been extensively discussed in the applied ethics literature. Typically, this discussion is focused on the use of genetic engineering to further human ends. However, genetic engineering can also be used in a way that does not solely benefit humans but rather improves the welfare of animals, thereby introducing new considerations into the moral debate.

Nevertheless, it is not clear that proposals involving improvements to the welfare of animals are any more palatable to the public than other applications of genetic engineering. Indeed, in most scholarly writing on the topic, the authors acknowledge either their own personal discomfort with the idea or the fact that the public finds the idea disturbing. Thus, there is a central tension around ethical discussions of the topic: on the one hand, the proposed changes seem to follow from many of the most prominent ethical frameworks for animals, but on the other hand, many people nevertheless find the idea morally objectionable.

Evolution of Genetic Engineering Technology

Direct methods of influencing an organism's genetic composition were first introduced in the 1970s. These initial methods of genetic engineering often utilized a bacterium (or a virus) as a carrier to transfer foreign genetic material to a target organism. This method was inefficient, and researchers were forced to limit their choice of target organisms to those that were susceptible to infection by specific bacteria and viruses. Consequently, various other genetic engineering techniques were developed. Microinjection, a process in which a micropipette is used to directly deliver foreign DNA into a cell, often a fertilized oocyte, was a commonly used method.

The aforementioned methods are examples of transgenesis, meaning that the introduced DNA is exogenous. A significant weakness of using a bacterium or virus carrier, microinjection, or other similar techniques is that they lack precision; the foreign genetic material is randomly integrated into an organism's genome. These methods of genetically engineering organisms were groundbreaking for the field, but they lacked elements necessary for efficient and widespread use.

Today, newer and more precise technologies are predominantly used in genetic engineering. Gene targeting technologies such as zinc finger nucleases (ZFNs), transcription activator-like effector nucleases (TALENs), and clustered regularly interspaced short palindromic repeats (CRISPR) systems are revolutionizing genetic engineering. These technologies are able to modify genomes by creating precise breaks in DNA and utilizing either homology-directed repair or nonhomologous end joining (NHEJ) to repair breaks. When NHEJ is used, the result is not transgenic: no genetic material from a foreign organism has been introduced. When these technologies are used in genetic engineering, the practice is referred to as genome editing. These new technologies allow for precise knock-ins, knockouts, and modifications, making genome editing vastly more efficient than previous methods of genetic engineering. Collectively,

these technologies have revolutionized the possible applications of genetic modification in plants and animals.

Applications of Genetic Engineering to Improve Welfare

Genetic engineering can improve animal welfare by increasing disease resistance, eliminating the rationale for painful procedures, or directly intervening on the psychology of animals. There are many opportunities for animal welfare to be improved through utilization of genome-editing technologies.

Disease Resistance

Poor health is a detriment to welfare. Diseases induce poor health and can be fatal. Genetic engineering can protect animals from some diseases through induced resistance and enhanced immune system effectiveness, thus improving animal welfare.

Mastitis is the bacterial infection of the mammary gland and occurs in many milk-producing female animals. Genetically engineering livestock could pose a solution to the problem of mastitis. ZFNs have been used to knock-in the human lysozyme gene into a cow gene that is highly expressed in the mammary glands, resulting in high levels of expression of lysozyme (Liu et al. 2014). This genetic modification resulted in cows that were 100% resistant to mastitis. Lysozyme plays a role in fighting bacterial infections and has also improved goat udder health after integration into goat genomes (Maga et al. 2006). This provides strong evidence for the possibility of successfully genetically engineering cows and goats for improved udder health.

Genetic engineering has also been utilized in an attempt to mitigate prion diseases, which are fatal neurodegenerative disorders caused by the accumulation of misfolded prion proteins (PrP). In cattle fibroblasts, TALENs and CRISPR-Cas9 have been used to successfully knockout *PRNP*, the gene that codes for PrP, though the long-term effects of this knockout on cow functioning are unknown (Choi et al. 2015). However, lab mice

have undergone a *PRNP* knockout with variable effects, ranging from nonexistent to severely disabling outcomes (Linden et al. 2008). Due to the associated welfare concerns, it is unlikely that a complete knockout of *PRNP* will be pursued in livestock, though disruption of the gene appears promising in reducing the prevalence of prion diseases.

Bovine tuberculosis (BTB) is a highly transmissible chronic infectious disease caused by *Mycobacterium bovis* (Wu et al. 2015). A mouse gene, *Ipr1*, has shown resistance to *Mycobacterium tuberculosis*, a bacterium related to *M. bovis* that is known to cause tuberculosis in humans (Pan et al. 2005). Variants in the human gene *SP110* were found to also be associated with resistance and susceptibility to tuberculosis (Tosh et al. 2006). This suggests that there is an association between the *Ipr1/SP110* genes and *M. tuberculosis* susceptibility across certain species. TALENs were used to knock-in the *Ipr1* gene to Holstein-Friesian genomes, resulting in cows which were resistant to the tuberculosis-causing bacteria (Wu et al. 2015).

Porcine reproductive and respiratory syndrome (PRRS) is a prevalent viral disease in pigs that results in various ailments to pig health such as respiratory distress, fever, stillbirths, and miscarriages. One exon in the *CD163* gene codes for the scavenger receptor cysteine-rich domain 5 (SRCR5) region, a crucial fusion receptor for PRRS virus (PRRSV). Using CRISPR-Cas9, a knockout of the exon in *CD163* that codes for SRCR5 was conducted in pig zygotes (Burkard et al. 2017). This produced piglets that were completely resistant to multiple PRRSV variants, providing evidence for the success of this application of genome editing.

Avian influenza virus (AIV) is an important disease in domestic chickens that can be transmitted to various other animals. Chicken embryo fibroblasts were genetically engineered to produce a “decoy” molecule that interfered with the virus’s ability to undergo replication (Lyll et al. 2011). The resulting chickens were not resistant to direct infection of the virus, but transmission of the virus to healthy chickens (both genetically engineered and nongenetically engineered) was prevented. Thus, this genetic modification resulted in an

alteration in transmission processes and consequently could act as a protective measure for flocks of chickens that would otherwise be susceptible to AIV transmission.

Eliminating Painful Life Events

There are a number of agricultural procedures commonly performed without the use of pain mitigation that raise serious concerns regarding animal welfare. One such procedure is the dehorning/disbudding of cattle, a common procedure in both the dairy and beef cattle industries. Physiological and behavioral measures show significant pain and stress are felt by animals during these events and for an extended period of time afterward (Faulkner and Weary 2000). Producers can use a combination of drugs to mitigate the resulting pain, but unfortunately many calves are still dehorned without pain mitigation (Stafford and Mellor 2005).

Genetic modification of animals could constitute a potential solution to cattle dehorning/disbudding and other painful aspects of an animal’s life. A potentially practical way to reduce the prevalence of dehorning is to genetically modify cows to induce a polled (hornless) phenotype. This is a naturally occurring phenotype, though it is rare in predominant breeds of dairy cattle. Using genome-editing technologies, a knock-in of the naturally occurring *POLLED* gene occurred in bovine embryo fibroblasts (Carlson et al. 2016). Two hornless male calves were born with good health and physiological functioning and no abnormalities in behavior or appearance. This provides evidence that genetic modification poses an opportunity to improve animal welfare through reducing the need for invasive surgeries such as dehorning.

In principle, similar approaches could be used to address welfare concerns associated with other painful procedures. Researchers are already investigating the possibility of using gene editing to produce boars with altered production of androstenone who thereby do not develop “boar taint.” This would eliminate the main rationale for castration, another common painful procedure often performed without analgesia. In addition to making modifications that would eliminate

human-caused painful events, researchers are also investigating the use of gene editing to eliminate aggression between livestock which can result in serious welfare problems.

Altering Consciousness

Instead of reducing the need for painful life events, some scholars have proposed using genetic engineering to change the experience of the livestock altogether. It should be noted that though these ideas raise interesting questions for ethicists, their possible application to livestock is currently far more speculative than the proposals of the previous sections. One common suggestion has been to genetically engineer animals so that they lack the capacity to feel pain or other negative experiences. Pain researchers have used genetic engineering to create mice with impaired Nav1.7 sodium channels that appear to be completely insensitive to painful stimuli, mimicking the effects of a mutation in humans that underlies a condition known as congenital insensitivity to pain (Gingras et al. 2014). People with this condition, like the mice, have normal touch sensation but completely lack the ability to feel pain. Further research found that giving the modified mice an opioid antagonist (a chemical that blocks the effects of opioids, including endogenous opioids) reestablished pain sensitivity, which led to the remarkable finding that giving a human with congenital insensitivity to pain an opioid antagonist caused that person to feel pain for the first time in her life at the age of 39 (Minett et al. 2015). Theoretically, genome-editing technologies could be used in other animals, such as livestock, to disrupt the activity of Nav1.7 in those animals. This could prevent the experience of pain in animals who might otherwise suffer.

Because pain plays a protective role, one obvious concern with this suggestion is that pain-free animals will fail to protect themselves from harm and thus endure serious health problems and possibly death. Various proposals have been put forward to address this concern. Shriver (2009), noting the difference between the sensory and affective dimensions of pain, has suggested that genetic knockouts that target the affective dimension of pain may eliminate the unpleasantness of

the pain sensation while still preserving some protective behaviors. David Pearce (1995) has proposed eliminating the pain system entirely but “reengineering” the reward system to facilitate behaviors previously facilitated by the pain system. These proposals are more speculative than those of the previous two sections, but studies thus far support the possibility that reducing or eliminating the experience of pain is a realistic application of genetic engineering.

History of the Ethical Debate

Some early scholarly articles relevant to the ethical debate about welfare engineering did not discuss genetic engineering but selective breeding. In 1981, Beilharz and Zeeb (1981) provoked controversy in the animal welfare community when they argued that using selective breeding to produce animals that are happy in confinement is preferable to changing conditions on farms. This was referred to as “fitting the horse to the harness.” In 1985, Ali and Cheng (1985) published a study on a genetic variation of chickens that are blind at birth. The authors tentatively suggested that the blind chickens might have some advantages over other chickens in intensive confinement since the blindness appeared to result in a decrease in aggression, a point later discussed in more detail in the ethics literature by Peter Sandoe and colleagues (1999). Reducing cannibalism in chickens would, in theory, be a welfare improvement over the status quo, but it is worth noting that Sandoe’s group later investigated and discovered the blind chickens in fact had serious welfare problems of their own. These examples did not involve genetic engineering but were influential on the ensuing debate since they involved proposals to change animals to be more adaptable to modern husbandry systems, rather than providing animals with environments that are suited for their original needs.

One of the earliest discussions in the philosophical literature of the idea of using genetic engineering to improve welfare was articulated in Bernard Rollin’s book *The Frankenstein Syndrome* which developed an idea he had briefly

mentioned in a previous paper. Rollin discussed the idea of genetically engineering animals to better fit animal husbandry systems, referencing the idea of chickens that are “ecstatic in battery cages” (1995, p. 192). Though Rollin noted that he found the idea repulsive, he suggested that it would not necessarily be morally wrong and wrote that “caring enough about the animals to try to engineer them so as to be happy” would be an improvement over the current mindset toward animals (ibid, p. 193).

Inspired by an earlier comment from Rollin, Gary Comstock (1992) described a hypothetical situation with an egg laying operation featuring genetically altered chickens with no eyes, ears, nose, or nerve endings and lacking all awareness. Comstock had previously written about attempts to engineer pigs with human growth hormone that resulted in a number of sickly and suffering animals, so he expressed concern that the testing required to produce particular alterations would involve serious welfare problems. However, he suggested that if we could instantaneously bring into existence the hypothetical unconscious “egg laying machine” chickens, “scientists would have no obligations to them, since the birds have neither feelings nor a future.”

Arguments in Favor of Genetic Engineering for Welfare

As noted above, humans have been shaping the genetic characteristics of livestock for millennia through selective breeding. Often human influence has been directed at breeding animals that are more beneficial to humans. However, there have also been cases where selective breeding has improved the welfare of animals, such as William Muir’s work breeding “kind gentle birds” using group selection. So perhaps the simplest reason for approving of genetic engineering for welfare is seeing it as continuous with previous methods for influencing the genetics of agricultural animals that one believes are acceptable. But variations on the proposal would appear to be compatible with many of the most prominent accounts of our moral obligations toward animals.

Utilitarian and Welfarist Arguments

If maximizing pleasure and minimizing pain are the only two moral imperatives relevant for our treatment of animals, the argument in favor of welfare engineering is straightforward. Current conditions in animal agriculture cause a great deal of suffering for the animals involved, and if gene editing can be used to reduce the net amount of suffering, then all things being equal we have a duty to substitute genetically engineered animals for the animals that are currently used.

However, there are complications with the utilitarian argument for welfare engineering. Some animals will presumably suffer during the development of the technologies. It is possible that the use of welfare engineering would prevent the shift to other alternatives that more extensively addressed welfare concerns such as dramatic reductions in meat consumption or the development of in vitro meat technologies. And, for proposals involving the alteration of experience, there would be epistemological challenges that could impede confidence that the animals actually had a diminished capacity to suffer.

Sentientism and Moral Standing Based on Psychological Capacities

Once we move away from utilitarian accounts, some of the arguments in favor of welfare engineering no longer follow. For example, on some animal rights’ views, we have an obligation not to cause any unnecessary harm to other animals or to use animals as a means to an end. On these views, a hornless cow raised for human ends still has rights that are violated by human actions. The fact that overall suffering is reduced would not make the practice any less objectionable if we are violating the rights of particular animals (although, arguably, it would also not make the practice any *more* objectionable than current animal husbandry).

However, many rights-based views are nevertheless sentientist views, which hold that conscious experience is a necessary condition for moral standing. As such, at least some of the welfare engineering proposals involving the alteration of consciousness would be compatible with these positions. If an animal is completely insentient, as in Comstock’s example, then the animal

has no moral standing on these views, and so it would be better to use insentient animals to produce food than to violate the rights of sentient animals.

In fact, this possibility is not limited to sentientist accounts. For any account that suggests that the moral standing of animals is based on psychological capacities, there is some hypothetical knockout that would eliminate those psychological capacities while allowing the animal to be raised for human purposes. Of course, whether or not those hypothetical examples can realistically be created is uncertain, but there are a broad range of views that should, in principle, be open to welfare engineering under certain circumstances.

General Objections to Genetic Engineering

Many of the objections to welfare engineering are more general arguments against genetic engineering. As noted above, the idea of using biotechnology to modify animals causes many people to react negatively. Various authors have attempted to either explain why these negative feelings should have some normative force or to provide other arguments for why we ought to avoid genetically engineering animals.

Unnaturalness

One of the most common reactions to genetic engineering is that it is unnatural or involves humans “doing things that humans were not meant to do.” Mary Midgley articulated one such position, writing, “To say that the change is unnatural is not just to say that it is unfamiliar. It is unnatural in the quite plain sense that it calls on us to alter radically our whole conception of nature” (2000, p. 12). There are two significant interrelated challenges facing approaches that appeal to naturalness to argue against genetic engineering in an agricultural context.

The first challenge is to come up with a plausible distinction between “natural” and “unnatural” that explains why certain forms of human activity in modern life are natural and others are not. This challenge is compounded in the

agricultural context by the fact that we have dramatically altered the behavior and physiology of agricultural animals over thousands of years through selective breeding and currently engage in practices such as giving animals growth hormones, antibiotics, and feed that their wild counterparts would never consume while often confining them in severely restricted environments. Thus, it can be a challenge to come up with a notion of “natural” that would lead to the conclusion that genetic engineering of animals is unnatural while maintaining that many other current agricultural practices are natural (of course, one might object to all modern agriculture on the grounds of naturalness).

The second challenge is providing an argument that establishes why the natural, as previously defined, should be seen as morally preferable to unnatural. There are many human activities that don’t fit the common conception of “natural” but seem to be morally praiseworthy. And there are many activities that *Homo sapiens* engaged in prior to the formation of modern civilization that would be extremely morally problematic by today’s standards. So it is not clear, without further argument, that we have strong reason to prefer “the natural” to “the unnatural.”

Religious Objections

Religious objections to genetic engineering often are associated with appeals to naturalness. On some of these accounts, what makes genetic engineering unnatural is the fact that humans are engaged in the activity of creating and shaping life, an activity that should be reserved for God or other divine entities. These objections, as they are traditionally formulated, still face the challenge of explaining why genetic engineering but not selective breeding should be considered “creating life” and also of explaining why we should think of unnaturalness as morally problematic. In addition to these challenges, of course, such claims require independent reasons for adopting the religious perspective.

Risks to Humans

Some endeavors using genetic modification have led to unforeseen environmental and welfare

problems. As such, it is not surprising that many people view the use of biotechnology in agriculture as a risky undertaking that could lead to unforeseen consequences that negatively impact human health or nutrition. The development of better gene-editing technologies has reduced some of the imprecision and the risks that previously accompanied genetic engineering. Nevertheless, a strong body of evidence exists suggesting that humans often fail to predict the full consequences of interventions in the natural world.

Telos

Importantly for the development of this debate, Bernard Rollin is the scholar most responsible for bringing the idea of *telos* into discussions of animal welfare. The *telos* of an animal refers to “the set of needs and interests which are genetically based and environmentally expressed, and which collectively constitute or define the ‘form of life’ or way of living exhibited by that animal, and whose fulfillment or thwarting matter to the animal” (1998, p. 162). Properly respecting an animal’s *telos* involves allowing it to engage in its natural set of behaviors.

Several authors have appealed to the notion of *telos* in order to criticize genetic engineering. The idea is that by altering animals’ genes, we are depriving them of their natural set of behaviors. However, as Rollin noted in his initial discussion, if you change the genetics of an animal, you are presumably also changing the animal’s *telos*, and as such you are not failing to respect an animal’s *telos* as long as you provide conditions that are well suited for the (new) phenotype. As such, there has been sustained debate about whether the notion of *telos* can support the suggestion that genetically engineering animals in a way that changes their behavioral drives is causing the animals harm.

Species Integrity and Dignity

Instead of appealing to Rollin’s notion of *telos* to suggest that an individual animal’s welfare is harmed by genetic modification, some authors instead reference the behaviors typical of a species. On this view, by depriving animals of activities that are common to their species, you are

doing something morally wrong not because you are harming the individual animal but because you are violating the integrity of the species.

A related idea is expressed by some authors as the concept of an animal’s dignity. Ortiz (2004) suggests that if you remove capacities from animals that allow them to sustain themselves in environments suitable for their species, you are failing to respect the dignity of those animals. She argues that dignity is distinct from welfare but nevertheless is part of what is *good for* the animal and as such concerns about dignity can sometimes trump the value of welfare. For example, she suggests that it is better to be a chicken with a species typical urge to nest confined in an environment where it is impossible to nest than to be a chicken lacking the urge to nest in the same environment, even if the latter chicken has better welfare.
